Behavior of Cavities in Pulmonary Tuberculosis Exhibit of serial roentgenograms of patients who presented tuberculous cavities in various parts of the lungs and the behavior of these cavities from time to time and their response to the different forms of accepted treatment

ISAAC H. ERB and GLADYS L. BOYD, Hospital for Sick Children Department of Pediatrics, University of Toronto, Toronto

Exhibit of pathologic specimens photomicrographs drawings and roentgenograms showing childhood pulmonary tuberculosis and bronchiectasis

CLARENCE L HYDE CARL R STEINKE and ASSOCIATES, Edwin Shaw Sanatorium, East Akron, Ohio

Cavity Closure in Pulmonary Tuberculosis Exhibit of (1) chart showing the importance of the closure of cavities, (2) roentgenograms and legends showing closure of cavities by conservative treatment, artificial pneumothorax, artificial pneumothorax and interpleural pneumolysis, phrenicectomy, combined phrenicectomy and artificial pneumothorax and thoracoplasty, (3) illustrations of failure to close cavities by the foregoing procedures and the reasons therefor

H HAROLD FELLOWS and ADA CHREE REID Metropolitan Life Insurance Company, New York

I Demonstration of the value of the routine fluoroscopic examinations in the detection of (a) early cases of pulmonary tuberculosis (b) lesions other than pulmonary tuberculosis (c) cases of advanced pulmonary tuberculosis without physical signs or symptoms II Demonstration of roentgenograms showing development of pulmonary tuberculosis in a previously healthy adult.

Section on Urology

Section exhibit committee RUSSELL S FERGUSON, chairman, New York, THOMAS D MOORE Memphis Tenn G J THOMPSON, Rochester, Minn, and D W MACKENZIE Montreal

HUGH H YOUNG, James Buchanan Brady Urological Institute, Johns Hopkins Hospital, Baltimore

Plastic Surgery of Lower Urageental Tract Exhibit consists of history and illustrations of cases of congenital malformations, epispadias, hypospadias, exstrophy of bladder incontinence of urine, pseudohermaphroditism and hermaphroditism showing condition before operation, surgical procedure and observations, photomicrographs, postoperative treatment and end results

C J BUCHER, R MANGES SMITH and THEODORE R FETTER Jefferson Medical College Hospital, Philadelphia

Differential Diagnosis of Some Common Renal Lesions—Pyogenic Infections, Tuberculosis and Malignancy Exhibit of roentgenograms, pathologic and bacteriologic specimens, case histories and clinical charts illustrating the lesions and the radiologic, bacteriologic and clinical evidence side by side

MOSES SWICK, Mount Sinai Hospital and Harlem Hospital New York

Congenital Anomalies of the Urinary Tract Exhibit of pyelograms depicting congenital anomalies of the urinary tract, diagnosis and differential diagnostic problems

JAMES F McCABE, LORENZ P HANSEN, DAVID SOLOWAY and DAVID R MORGAN, Jefferson Medical College, Philadelphia

Anterior Pituitary-Testis Endocrine Relation in the Human Being Exhibit of diagrams showing methods used in the chemical extraction of hormones from the urine, methods of testing for testis hormone by injection of capons, charts of capon comb growth obtained in various pathologic states, photographs of patients and of capons photomicrographs of ovaries of immature female mice illustrating reactions to anterior pituitary extract

JOHN S LEWIS JR. and EDGAR C BAKER Youngstown Hospital Association Youngstown Ohio

The Lower Ureter (as shown by serial urograms) Exhibit of transparencies of cases illustrating changes or lack of change in the lower ureter immediately following retrograde injection of opaque mediums

C C HIGGINS Cleveland Clinic Cleveland

Transplantation of Ureters Exhibit of drawings models and roentgenograms illustrating different methods of ureteral transplantation with experimental observations and clinical results with a new method

DAVID W MACKENZIE and ALEXANDER B WALLACE, Urological Department, Royal Victoria Hospital Montreal

Lymphatic Studies Relation of Lower Urinary and Genital Tracts to Renal Infections I Anatomic (a) demonstration of normal lymphatics of rabbits and method of preparation (b) demonstration of comparative lymphatic anatomy in fetus

II Experimental (a) demonstration of absence of lymphatic absorption from intact mucosa of bladder, (b) demonstration of lymphatic spread of dye after injection to pelvic organs, (c) demonstration of lymphatic absorption from zones of ureter, (d) demonstration of lymphatic absorption by roentgenograms

Section on Orthopedic Surgery

Section exhibit committee PAUL N JEPSON, chairman, Philadelphia, A LEO BRETT, Boston, ARTHUR WEILAND, Miami, Fla and R I HARRIS Toronto

The Section on Orthopedic Surgery in addition to other exhibits is presenting a group of exhibits on chronic arthritis In an area adjoining the exhibits a special motion picture program will be shown

PAUL N JEPSON, Orthopedic Department, University of Pennsylvania School of Medicine, Philadelphia

Gill Plate Graft in Treatment of Ununited Fractures of Long Bones Exhibit of roentgenograms and drawings of bones that have been cut, showing shape of graft and how to reverse and hold in place, including femur, tibia, humerus, radius, ulna and clavicle with explanatory notes

J DEWEY BISGARD, University of Nebraska School of Medicine, Omaha

Longitudinal Growth of Long Bones Exhibit shows (1) measurements of longitudinal growth of the principal long bones of goats (2) growth disturbances produced by damage to the epiphyseal cartilage causing deformities of shortening, (3) growth disturbed by x-ray and radium radiation, (4) questions of compensatory overgrowth, (5) clinical illustrations of problems

J P LORD R D SCHROCK and H F JOHNSON, Orthopedic Department, University of Nebraska Medical College Omaha

Bone Tumors Exhibit of transparent negatives showing x ray photographs and photomicrographs of bone tumors classified according to Registry of Bone Sarcoma

E P CORSON-WHITE, IRVIN STEIN, RALPH S BROWER and LASLO KAJDI Zoological Society of Philadelphia and Orthopedic Hospital, Philadelphia, and Johns Hopkins Hospital, Baltimore

Diseases of Disturbed Bone Metabolism in Monkeys and Man Charts illustrating metabolic studies and roentgenograms of osteomalacia, von Recklinghausen's disease and a condition simulating Paget's disease in monkeys, produced by variations in calcium, phosphorus and vitamin D in diets that gave a neutral, acid or alkaline ash, roentgenograms and charts illustrating treatment of Paget's disease, osteomalacia and von Recklinghausen's disease in man, based on dietary principles

F J GAENSLER, Milwaukee

Spiking of Fractures of the Neck of the Femur Exhibit showing (1) a method of reducing fractures of the neck of the femur (2) a method of taking anteroposterior and lateral roentgenograms of the hip without shifting the position of the patient (3) a method of internal fixation by means of spikes introduced subcutaneously

LEWIS CLARK WAGNER, Hospital for Ruptured and Crippled, New York

Posterior Bone Block of Ankle for Paralytic and Spastic Drop Foot Exhibit of specimens and charts describing the operation for bone block on the ankle

A LEO BRETT Boston

Corrective Osteotomy of Tibia for Adult Genu Recuratum Exhibit of photographs, drawings and roentgenograms showing underlying bony mechanopathology drawings of operation, roentgenograms before and after operation, corrective intracapsular osteotomy elevating the anterior table of the tibia

WILLIAM T GREEN, Children's Hospital of Boston, Boston
Osteomyelitis in Infancy Exhibit of roentgenograms, charts, tissue specimens and stained preparations showing the difference between the osteomyelitis in infants (under 2 years) and that of older individuals

FRANK R. OBER and ARTHUR T. LEGG, Children's Hospital of Boston, Boston

Operative Treatment of Polyomyelitis Exhibit of drawings of operative procedures and photographs of patients before and after operation, showing the operative procedures available in the treatment of deformities of infantile paralysis

JOSEPH BUCHMAN, Hospital for Joint Disease, New York
Healing in Osteomyelitis Following Maggot Therapy Exhibit of roentgenograms showing appearance of bones before the institution of maggot therapy and late after-results

BENJAMIN KOEHN and M. T. KOEHN, Jewish Hospital and Bethel Hospital, Brooklyn

Unusual Skeletal Tumors Exhibit of roentgenograms, photomicrographs and macrophotographs of biopsy and autopsy specimens, clinical history and review of literature dealing with plasma cell myeloma, primary hepatoma with bone metastases, giant cell tumor of spine, thyroidal metastasis, subcutaneous glioma tumor and multiple enchondroma affecting all skeletal bones

DAVID SASHIN, Hospital for Joint Diseases, New York

Relation of Pathologic Changes in the Intervertebral Disks to Low Back Pain Exhibit of gross formaldehyde and macerated specimens, microscopic sections, charts, photographs and roentgenograms showing intervertebral disk herniations, vascularizations, fibrosis and calcification of intervertebral disk substance, mounted macerated specimens illustrating the effect of a narrowed degenerated intervertebral disk on the articular facets and on the normal lumbar curve

EDGAR M. BICK, Hospital for Joint Diseases and Mount Sinai Hospital, New York

Common Soft Tissue Tumors of the Extremities Exhibit of charts, illustrations and photomicrographs depicting the clinical aspects of soft tissue tumors of the extremities, their preponderant locations, age of greatest occurrence, duration and certain physical characteristics, as an aid to clinical preoperative differential diagnosis

PAUL C. CORONNA, New York University College of Medicine, New York

New Type of Reconstruction Operation for Old, Ununited Fracture of the Hip Exhibit of roentgenograms, models and drawings showing preoperative and postoperative cases and stages of operation

Motion Pictures The following motion pictures will be presented on a definite schedule

ARTHUR T. LEGG, Boston: "Early After-Care of Polio myelitis"

WILLIAM T. GREEF, Children's Hospital of Boston, Boston: "The Care of the Joints in Atrophic Arthritis of Children"

PAUL B. MAGNUSEN, Northwestern University, Chicago: "Continuation of Arthritic Symptoms Due to Mechanical Irritation of Arthritic Residue and Prolonged Slight Trauma"

VOIGT MOONEY, Allegheny General Hospital, Pittsburgh: "Studies of the Human Locomotion"

EXHIBITS ON CHRONIC ARTHRITIS

M. H. DAWSON, A. B. FERGUSON, H. H. KASANACH and G. D. TAYLOR, Presbyterian Hospital, New York Orthopedic Dispensary and Hospital, New York

Roentgenologic Observations in Various Forms of Chronic Arthritis Exhibit of roentgenograms, drawings and charts showing the characteristic roentgenologic appearances in the following forms of chronic arthritis: rheumatoid arthritis, osteoarthritis, gout, tuberculous arthritis, gonococcal arthritis, Marie Strümpell spondylitis, Still's disease

WALLACE S. DUNCAN and RUSSELL L. HADEN, Departments of Medicine and Orthopedic Surgery, Cleveland Clinic, Cleveland

Chronic Arthritis Exhibit of wax models of hands illustrating chronic rheumatoid (atrophic) arthritis and chronic hypertrophic arthritis (osteoarthritis) with roentgenograms and clinical histories

JOHN W. GRAY, WILLIAM G. BERNHARD and CECIL H. GOWEN, Hospital St. Barnabas, Newark, N. J.

Chronic Arthritis Exhibit of specimens, photomicrographs, roentgenograms and charts showing pathologic changes, clinical types, classification, differential diagnosis, clinical manifestations, bacteriology and treatment

Section on Gastro-Enterology and Proctology

Section exhibit committee: A. H. AARON, chairman, Buffalo, THOMAS L. ALTHAUSEN, San Francisco, J. A. BARGEN, Rochester, Minn., RUSSELL S. BOLES, Philadelphia, HERBERT T. HAYS, Houston, Texas, ERNEST C. CLEAVER, Toronto, and R. H. M. HARRIS, Montreal

The Section on Gastro-Enterology and Proctology, in addition to an extensive array of exhibits dealing with various phases of gastroenterology and proctology, is participating in the Symposium on Cancer

GROUP EXHIBIT: *The Small Intestine* University of Pennsylvania School of Medicine, Philadelphia. Exhibit showing the physiology, chemistry and pathology of the small intestine, including the physical, chemical and radiologic observations on the experimental animal and man and apparatus working on the human being and in the dog with chimeographic tracings, charts and tubes, and roentgenographic illustrations. The following individuals will participate: Section of Gastro-Enterology: T. GRIFR. MILLER, W. OSLER ABBOTT and KATHERINE OS. LISON. Medical Clinic: WILLIAM G. KARR, Department of Research Surgery: J. S. RAVIN, CHARLES G. JOHNSON and P. J. MORRISON, Department of Physiologic Chemistry: D. WRIGHT WILSON, F. A. CAJORI and EDWIN J. DEBEER, Department of Radiology: HENRY K. PANCOAST, EUGENE P. PEN. BERGRASS, PHILIP J. HODGES and J. ROBERT ANDREWS

GROUP EXHIBIT: *Sodium Chloride Therapy in Relation to Hypochloremia, Isotemia and Dehydration* Abington Memorial Hospital, Abington, Pa. Exhibit consisting of charts and experimental work on dehydration, hypochloremia and azotemia, cases illustrating this syndrome in bicarbonate intoxication, high obstructions, renal disease, toxemias of pregnancy and diabetes. The following individuals will participate: WILLIAM G. KARR and JOHN ELMAN, Surgery; DAMON B. PFEIFFER, CAVIN SMYTH JR., IRVING M. BOYKIN, J. WALTER LEYERER, Medicine; GEORGE MORRIS PIERSON, HARRY B. WILNER, HARRY L. BOCKUS, JOSEPH STOKES JR., JOHN H. WILLARD, THEODORE S. WILDER, JOHN B. POLANSKY, Urology; ALEXANDER RANDALL and EDWARD W. CAMPBELL

GROUP EXHIBIT: *Studies on Crystalline Vitamin B₁* Exhibit will include the method of isolation from rice polishings, chemical studies of isolated substances, cleavage products, a model of its structure, a number of studies demonstrating its effect on animals and a group of studies on human beings. The following individuals will participate: Chemistry: ISOLATION: ROBERT R. WILLIAMS, ROBERT E. WATERMAN, JOHN C. KREBSZTESY. Sulfur Chemistry and Thiazole Nucleus of Vitamin: H. T. CLARK and SAMUEL GURIN. General Chemical Structure of Vitamin: EDWIN R. BUCHMAN and ROBERT R. WILLIAMS. Ultraviolet and Potentiometric Studies: A. E. RUFILE. Analytic Data: OSCAR WINTERSTEINER. Medical and Physiologic Chemical Experiments: MARTIN G. VORHAUS, ROBERT R. WILLIAMS and SIDNEY BERKOWITZ. Animal Experiments: ROBERT E. WATERMAN and MARION AMMERMAN. Bio-Assays: MARION AMMERMAN

HERBERT T. HAYS, HARRY B. BURR and J. WADE HARRIS, Houston, Texas

Lymphogranuloma Inguinale Exhibit of placards, photographs and drawings with mounted gross specimens

COLLIER F. MARTIN, University of Pennsylvania Graduate School of Medicine, Philadelphia

Lymphopathia Venerea Exhibit of photomicrographs, photographs, diagrams and charts illustrating origin and clinical course, age, sex and race, Frei test and associated pathologic changes and complications, anatomic specimens showing the lymphatic and blood supply of the urogenital and rectal areas

MAURICE F DWYER, Mason Clinic, Seattle

Gastro-Intestinal Lesions Exhibit of roentgenograms of certain gastro-intestinal lesions, each accompanied by nature size colored plaster models of the stomach or colon correlating the roentgenologic surgical and pathologic changes in the lesion Duodenal ulcer, gastric ulcer, gastric carcinoma at various sites, benign gastric tumors and carcinoma and polyposis of the colon are depicted.

MARTIN E. REHFUSS, Jefferson Medical College, Philadelphia

Gastrophotography Exhibit of actual photographs of the interior of the stomach, roentgenograms of these cases, abstracts of history, charts with complete description of surgical and pathologic changes

ASHER WINKELSTEIN, Mount Sinai Hospital, New York

Continuous Intragastric Milk Drip—A New Therapy for Peptic Ulcer Exhibit of apparatus, method of therapy and charts showing studies in gastric secretion on which the method is based, particularly nocturnal gastric secretion, curves before and after treatment, roentgenograms showing results

A. M. SNELL, J. F. WEIR, J. D. CAMP, C. H. WATKINS and MILDRED ADAMS, Mayo Foundation for Medical Education and Research, Rochester, Minn.

Idiopathic Steatorrhea (nontropical sprue) Exhibit of transparencies showing photographs of patient, charts of gastric acidity, metabolism of fat and nitrogen calcium and phosphorus disturbances, hematologic changes, and results of treatment, roentgenograms showing changes in the intestine and bone Evidence is presented to suggest relationship to celiac disease, tropical sprue and pernicious anemia

MANFRED KRAEMER and MAURICE ASHER, Newark N. J.

Management of Nonspecific Ulcerative Colitis Exhibit of charts, roentgenograms, colored proctoscopic drawings and photographs presenting the clinical picture of nonspecific ulcerative colitis and its treatment together with the role of serums, vaccines, diets, rest, medication and ultraviolet irradiation in the therapeutic armamentarium.

SEALE HARRIS, Birmingham, Ala.

Disorders of Insulin Secretion Diabetes Mellitus (Hypo-Insulinism) Dysinsulinism and Hyperinsulinism Exhibit of charts, diagrams, simplified diets and lantern slides illustrating cases of pituitary thyroid, adrenal, hepatic and pancreatic diabetes mellitus Clinical type of hyperinsulinism, mild moderately severe and severe cases Gastro-intestinal manifestations Neuropsychiatric hyperinsulinism. Convulsive seizures and hyperinsulinism Dysinsulinism

WILLIAM A. SWALM, Temple University School of Medicine, Philadelphia

Practical Consideration of Coprology (Exclusive of Parasites) Exhibit on (1) normal and pathologic physiology of the gastro-intestinal tract with special regard to the feces, (2) estimation of transit time, (3) intestinal test diet, (4) charts, paintings photographs and casts referable to the macroscopic, chemical, microscopic and bacteriologic examination of the feces, (5) charts concerning hypermotility and functional disorders of the colon and sample diet for these conditions including roughage and bland bulk of various foods

RUDOLF SCHINDLER, University of Chicago, Chicago

Development of Gastroscopy Exhibit of historic instruments with short description, books, colored pictures and motion pictures showing the technic of gastroscopy

ARTHUR SCHIFFRIN, Mount Sinai Hospital, New York

Pathology of the Liver and Biliary Tract Exhibit of gross specimens and photomicrographs representing the pathogenesis of diseases of the liver and biliary tract, showing the various types of cirrhosis, graphic representation of a classification of the cirrhosis, pathology of 'catarrhal jaundice' and detailed correlation between the clinical observations and interpretations and the morphologic aspects of the specimens exhibited

N. B. DREYER, Dalhousie University, Halifax N. S.

Study of Intestinal Movements in Situ in the Cat Exhibit shows a record of movements from an intestinal loop in a decerebrated or anesthetized cat demonstrating the effects of drugs

B. B. VINCENT LYON, Philadelphia

Microscopy of Oral, Gastric Duodenal and Biliary Tract Exhibit of photomicrographs demonstrating normal and abnormal cytology of mouth, esophagus, stomach, duodenum and biliary tract, photomicrographs of commoner foods in various stages of digestion, microscopy of fresh biliary drainage, with differential diagnostic interpretations, differentiation of calculous from noncalculous cholecystitis

THOMAS E. JONES, Cleveland Clinic, Cleveland

Anorectal and Colonic Cancer For description of exhibit see Symposium on Cancer

Section on Radiology

Section exhibit committee S. W. DONALDSON, chairman, Ann Arbor, Mich., VINCENT W. ARCHER, University, Va., JOHN T. FARRELL JR., Philadelphia, and W. A. JONES, Kingston Ont.

The Section on Radiology has contributed largely to the symposium on cancer as well as to various other section exhibits. In addition to the exhibits listed here, a large amount of radiologic material will be found in other parts of the hall.

ALBERT SOILAND, W. E. COSTLOW and O. N. MELAND, Los Angeles

Selective Radiologic Treatment of Neoplastic Diseases Exhibit of transparencies showing pioneer work in irradiation (1901-1910), transition period, modern period and pictures of patients before and after treatment, photomicrographs of tumors, with brief outline of each case or group, including cancer of the skin, oral and pharyngeal cavities, sinuses, breast, uterus and others, together with a few sarcomas of various types

J. CURRIE McMILLAN, Winnipeg, Manit.

Exhibit consisting of roentgenograms showing (1) visualization of the biliary tract with iodized poppy-seed oil, (2) fibrocystic bone disease (parathyroid tumor)

ARTHUR C. SINGLETON, Toronto General Hospital, Toronto

Prepyloric Gastric Lesions Exhibit of transparencies illustrating prepyloric cancer, prepyloric ulcer, gastric syphilis, hypertrophic pyloric stenosis pylorospasm and prepyloric deformity due to extragastric lesions

BEDE J. HARRISON, Vancouver General Hospital, Vancouver, B. C.

New Method of Orientation Applicable to the Body and the X-Ray Beam Exhibit of series of prints showing the application of method to the position of the patient and to the position of different parts of the body, description of the central ray with regard to the patient prints showing method of determining the point of incidence of the central ray for use with the method, prints of different parts of the body, with the details of the position of the patient and the portion of the ray described according to the method.

J. E. GENDREAU, Institut du Radium Montreal, Que.

Intestinal Roentgenograms with Colloid Thorium Compounds Exhibit of roentgenograms showing results of the thorium technic, with a comparison of the barium technic.

H. DABNEY KEER and EDWIN L. RYBINS, Department of Roentgenology, State University of Iowa, Iowa City

Roentgen Diagnosis of Neoplasms of the Kidney in Adult Life and Childhood Exhibit deals with tumor of the kidney, with pyelographic and other roentgenologic observations, several cases of tumors in adults and in children are presented with tissue differential diagnosis from blood clot and metastatic invasion of the kidney are pointed out

I. SETH HIRSCH, New York

Kymoroentgenography (A Method of Recording Cardiac Movement by Roentgen Ray) Exhibit of charts and diagrams illustrating the principles of kymography roentgenograms of normal and pathologic hearts, showing records of movements, kymoscope for making visible the cardiac movements from the roentgenkymogram

RAPHAEL POMERANZ, Newark, N. J.

The Mesentery Exhibit showing visualization of liver, spleen, normal and pathologic peritoneum and mesenteric lymphatics in animals with microscopic observations. New method of arteriography of the mesentery in animals, roentgenograms of human cases, with operative observations and special reference to mesenteric pathologic changes. (1) mesenteric cyst, (2) two different types of intussusception in children, (3) inflammatory mass in the right lower quadrant, differential diagnosis from neoplastic lesion, (4) gelatinous carcinoma of cecum growing around sigmoid, (5) early carcinoma of sigmoid with long mesosigmoid, (6) carcinoma of descending colon, with clinical and radiologic symptoms of small bowel obstruction.

JOHN RUSSELL CARTY, New York Hospital, New York

Diagnostic Scap of Soft Tissue Radiography Exhibit of roentgenograms of normal and pathologic soft tissue, illustrating the diagnostic possibilities in the radiographic exploration of soft tissue, essential technical features are briefly reviewed.

JACOB GERSHON-CORNE and ALBERT STRICKER, Philadelphia Skin and Cancer Hospital, Philadelphia

Roentgenographic Studies of Female Normal Breast Exhibit of roentgenograms of normal female breasts made in subjects from 10 to 80 years of age at the beginning and midway between the menstrual cycles, showing the variation in the appearance of the normal breasts roentgenographically and the general characteristics for each age group related particularly to puberty, young adult (unmarried), young adult (married), adult (child bearing), the climacteric and the postclimacteric periods.

W. EDWARD CHAMBERLAIN and BARTON R. YOUNG, Temple University School of Medicine, Philadelphia

Hodgkin's Disease—Unusual Manifestations and Sources of Error in Diagnosis Exhibit showing clinical data, roentgenograms, laboratory observations, photographs and photomicrographs of biopsy and autopsy material dealing with cases in which Hodgkin's disease was not suspected because the presenting symptoms and clinical appearances suggested some other condition. The protean manifestations of the disease are brought out to observers' attention by exhibiting cases in which the disease localized itself in the breast, spleen, bones, skin or lungs leading clinicians to believe they were dealing with primary conditions. Diagnoses such as cancer of the breast, malaria, scabies and tuberculous adenitis were made.

SHERWOOD MOORE, the Edward Mallinckrodt Institute of Radiology, Washington University School of Medicine, St. Louis

New Metabolic Disorder and Its Pathognomonic Radiologic Signs in the Skull Exhibit of roentgenograms of skulls and anatomic material, photographs of patients and specimens, abstracts from case histories, plaster reproductions of anatomic specimens and certain tribulations.

LEE A. HADLEY, Syracuse University Medical School, Syracuse, N. Y.

Apophysal Subluxation—Disturbances in and About the Intervertebral Foramen Causing Back Pain Exhibit of anatomic specimens, microscopic sections and roentgenograms illustrating conditions that cause both local and referred pain by disturbances in and about the intervertebral foramen.

HARRY H. BOWING and ROBERT H. FRICKE, Mayo Clinic, Rochester, Minn.

Radium Treatment of Carcinoma of the Uterine Cervix, the Braken Dose Method For description see Symposium on Cancer.

MAX CUTLER, Tumor Clinic, Michael Reese Hospital, Chicago

Carcinoma of the Mouth: Causation and Treatment For description see Symposium on Cancer.

B. P. WIDEMANN and J. L. WEATHERMAN, Radiologic Clinic, Philadelphia General Hospital, Philadelphia

Value and Limitation of Roentgen Rays and Radium in the Treatment of Cancer For description see Symposium on Cancer.

G. E. RICHARDS, Ontario Institute of Radiotherapy, Toronto General Hospital, Toronto

Radiation Therapy in Cancer For description see Symposium on Cancer.

M. H. DAWSON, A. B. FERGUSON, H. H. KASABACH and G. D. TAYLOR, New York

Roentgenologic Observations in Various Forms of Chronic Arthritis For description see Exhibits on Chronic Arthritis under Section on Orthopedic Surgery.

E. H. SHANNON, St. Michael's Hospital, Toronto, Ont.

Accessory Nasal Sinuses For description see Section on Laryngology, Otology and Rhinology.

ROBERT P. BALL, Broness Erlanger Hospital, Chattanooga, Tenn.

Roentgen Pelvimetry and Fetal Cephalometry For description see Section on Obstetrics, Gynecology and Abdominal Surgery.

A. HOWARD PIRIE, Royal Victoria Hospital, Montreal, Que.

Reading and Seeing Pictures with Eyes Closed For description see Section on Ophthalmology.

Symposium on Cancer

The symposium on cancer is made up of exhibits contributed by the Section on Surgery, General and Abdominal, the Section on Obstetrics, Gynecology and Abdominal Surgery, the Section on Laryngology, Otology and Rhinology, the Section on Pathology and Physiology, the Section on Gastro Enterology and Proctology, and the Section on Radiology, together with other exhibits and motion pictures. There will also be found in other parts of the hall additional exhibits dealing with cancer and similar neoplasms.

LOUIS I. DUBLIN, Metropolitan Life Insurance Company, New York

The Trend of Cancer—Incidence, Mortality and Curability Exhibit of charts showing cancer deaths in the United States compared with other causes, chances at each age of eventually dying from cancer, chief sites of cancer by sex, by age groups, trend of cancer death rate by site, by age groups, curability of cancer in certain sites, as reported in recent medical literature.

CHARLES A. BEHNEY and DOUGLAS P. MURPHY, Department of Obstetrics and Gynecology, University of Pennsylvania School of Medicine, Philadelphia

Carcinoma of the Cervix—Its Early Detection Exhibit showing illustrations of lesions often associated with carcinoma, early carcinoma, gross specimens, photomicrographs, colposcope and biopsy instruments.

CHARLES C. NORRIS, FRANCIS S. DUNNE and PENDLETON TOMPKINS, Department of Obstetrics and Gynecology, University of Pennsylvania School of Medicine, Philadelphia

Carcinoma of the Cervix—An Analytic Study Exhibit of charts, depicting the frequency, diagnosis, treatment, effect of preceding operation, pregnancy and follow up of carcinoma of the cervix, other conditions are presented for comparison by means of pathologic specimens in natural color, showing both rare and unusual conditions and especially typical conditions.

R. W. TEAHAN, W. S. HASTINGS, E. E. DOWNS and H. WAYMACK, Jeanes Hospital, Philadelphia

Carcinoma of the Cervix Uteri Exhibit of gross specimens, photomicrographic transparencies, roentgenograms, drawings, graphs and charts of carcinoma of the uterine cervix, showing the histology, gradation, metastases, complications, methods of treatment and results.

THOMAS E. JONES, Cleveland Clinic, Cleveland

Anorectal and Colonic Cancer Exhibit of wax models of specimens and charts descriptive of the one stage abdominoperineal operation.

HARRY H. BOWING and ROBERT E. FRICKE, Mayo Clinic, Rochester, Minn.

Radium Treatment of Carcinoma of the Uterine Cervix—The Braken Dose Method Exhibit of transparencies dealing with cancer of the cervix, incidence, classification, discussion of

various radium therapy technics, and the broken dose method of treatment, drawings of illustrative cases during the actual courses of treatment with explanations and a series of charts showing the late results obtained during the first decade (1915-1925)

NORMAN TREVES, Memorial Hospital, New York

Inflammatory Carcinoma of the Female Breast Exhibit of wax models taken from living patients water color illustrations of inflammatory cancer, photographs and photomicrographs and charts showing results of treatment and various diseases of the breast that may simulate inflammatory carcinoma Inflammatory carcinoma of the female breast appears to be a distinct clinical phase of breast cancer and it does badly if treated surgically In fact, surgery is contraindicated, irradiation offers the only hope of palliation

WILLIAM J HOFFMAN and GEORGE T PACK Memorial Hospital, New York

Carcinoma of the Duodenum Exhibit of transparencies illustrating incidence, symptoms, physical signs, radiographic appearance, diagnosis, pathology and treatment of carcinoma of the duodenum

MAX CUTLER, Tumor Clinic, Michael Reese Hospital, Chicago

Carcinoma of the Mouth—Causation and Treatment Exhibit of apparatus and charts dealing with 1 Causative factors demonstration of apparatus used for the measurement of electrical potentials in the mouth, charts indicating results of tests made in a large series of patients and a series of controls 2 Treatment special technic of preparation of radium moulds in the treatment of cancer of the mouth

RAYMOND S ROSEDALE and DONALD R MCKAY, Buffalo City Hospital, Buffalo

Primary Lung Cancer—Clinical, Pathologic and Roentgenologic Study Exhibit of charts to illustrate the location of tumor, cell type, bronchial constriction, metastases and associated lung changes—pneumoconiosis, fibrosis, tuberculosis, atelectasis, emphysema, abscess, bronchiectasis, empyema Charts to illustrate age, sex, race, occupational incidence the clinical symptoms and signs, radiologic, bronchoscopic and biopsy observations and pathologic processes that mask or obscure the clinical or radiologic picture of tumor Representative case histories with transparencies of roentgenograms, gross lung tumors and photomicrographs Bronchoscopic view of bronchogenic carcinoma in a manikin with electrically actuated artificial lung

L H CLERF B L CRAWFORD and R M LUKENS, Jefferson Hospital, Philadelphia

Neoplasms of the Larynx Exhibit of photomicrographs photographs, drawings, records, statistics and transparencies emphasizing the importance of early diagnosis of laryngeal neoplasms, particularly carcinoma, neoplasms of the larynx illustrating various types of carcinoma, also benign neoplasms

B P WIDMANN and J L WEATHERMAN Radiological Clinic, Philadelphia General Hospital, Philadelphia

Value and Limitations of Roentgen Rays and Radium in the Treatment of Cancer Exhibit of photographs, charts and drawings illustrating results of various technical procedures for administering roentgen rays and radium in the treatment of cancer lesions involving all anatomic sites, including early and late cancers classified according to the microscopic character and cellular differentiation and results obtained with various technics and doses impressions on the results of higher voltages higher filtrations with special reference to the Coutard technic of treating intra-oral cancers discussion of a wide range of technical procedures that can be employed in the treatment of skin intra-oral cervix and breast cancer

JACK MASON HUNDLEY JR HENRY J WALTON and GRANT E. WARD, Oncological Clinic University of Maryland, Baltimore

Combined Therapeutic Measures in the Treatment of Malignant Conditions Exhibit of drawings photographs wax moulds and motion pictures covering the use of the roentgen ray radium and electrosurgery in the treatment of various types of malignant disease

G E RICHARDS University of Toronto and Ontario Institute of Radiotherapy and Department of Radiology, Toronto General Hospital, Toronto

Radiation Therapy in Cancer Exhibit of transparencies illustrating methods of treatment and results obtained in various types of cancer by radiation therapy

Motion Picture E E SHEPLEY, Saskatoon Hospital, Saskatoon, Sask 'An Effective Offensive'

OTHER EXHIBITS ON CANCER

ALBERT SOILAND, W E COSTLOW and O N MELAND, Los Angeles

Selective Radiologic Treatment of Neoplastic Diseases For description see Section on Radiology

AMERICAN SOCIETY FOR THE CONTROL OF CANCER, New York
Cancer of the Uterus For description see Educational Classification

RALPH POMERANZ Newark N J

The Mesentery For description see Section on Radiology

EDUCATIONAL CLASSIFICATION

Government and National Organizations

The educational exhibits include those exhibits from national and state organizations and government institutions which are put on in the name of the institution rather than the individuals and which are intended to show progress in the particular activities with which those institutions deal

These exhibits are not open to medal awards, but a special certificate of merit is presented to the best exhibit in this classification

AMERICAN SOCIETY FOR THE CONTROL OF CANCER, New York

Cancer of the Uterus Exhibit consisting of wax models and charts showing classification of various stages, results of treatment and methods of prevention Maps of the United States showing the activities of the American Society for the Control of Cancer in several states and the progress of cancer control that has taken place in the United States since 1933

NATIONAL TUBERCULOSIS ASSOCIATION, New York

Costs of Tuberculosis Exhibit showing a series of statistical graphs, based on a study of costs of hospitalization loss of wages and so on in relation to time, diagnosis, use made and other factors

UNITED STATES PHARMACOPEIA

The New (Eleventh Revision) of the United States Pharmacopeia Exhibit of new assay methods for Pharmacopeial preparations medicinal products added to the Pharmacopeia, demonstration of a new cathartic biologic assay method studied for possible Pharmacopeial use, illustrations of Pharmacopeial revision methods

AMERICAN PHARMACEUTICAL ASSOCIATION Washington, D C

The National Formulary Exhibit of some of the more important and interesting additions to the new National Formulary, particularly items suitable for prescription practice

AMERICAN FEDERATION OF ORGANIZATIONS FOR THE HARD OF HEARING Washington, D C

Exhibit of posters charts and maps calling attention to the work of the federation, pamphlets pertaining to the work of the hard of hearing (educational, vocational and recreational)

COMMITTEE ON DEAFNESS PREVENTION AND AMELIORATION, American Academy of Ophthalmology and Otolaryngology

Deafness Prevention and Amelioration Exhibit of charts, diagrams photographs and motion pictures illustrating the need of efforts in the field of deafness prevention and amelioration modern methods of detection of hearing loss including instruments used in this work demonstration of hearing tests by modern methods methods of ameliorating the condition of the deafened through education, rehabilitation and the use of mechanical hearing aids

BUREAU OF ENTOMOLOGY AND PLANT QUARANTINE, U S Department of Agriculture, Washington, D C

(a) *Maggots in Treatment of Osteomyelitis* (b) *Honey as a Food* (a) An exhibit showing recent developments in the use of maggots for the treatment of osteomyelitis and other diseases of man and animals, also on the screw worm as a cause of myiasis in man (b) The chemical analysis of honey from a dietetic standpoint

AFRICAN SOCIAL HYGIENE ASSOCIATION, New York

Diagnosis of Primary Syphilis Exhibit of photographs, charts, motion picture, stained specimens for the microscope, dark field microscope and specimens presenting the clinure of syphilis, *Spirocheta pallida*, the methods of collecting specimens of chancre fluid, differential diagnosis of primary syphilis, the advantages of dark field diagnosis as compared with indurum and other staining methods, the practicability of mail transportation of specimens for diagnosis, and of central diagnostic laboratory facilities, and the importance of earliest diagnosis and treatment of syphilis

MEDICAL SOCIETY OF NEW JERSEY, Trenton

Exhibit showing 1 Organization plan of state and county societies 2 Coordination of state and county projects 3 Cooperation with state and county agencies 4 Legislation supervision and influence 5 Specific projects for the current year 6 Analyses of New Jersey health problems (graphic and statistical data on health conditions and needs at this time) 7 Procedures in vogue at present in preventive program 8 Forms and records used 9 Difficulties encountered 10 Results accomplished and the criteria used in measuring them

AMERICAN HOSPITAL ASSOCIATION, Chicago

Exhibit of charts, books, package libraries and other material covering the subject of hospital operation and maintenance.

AMERICAN OCCUPATIONAL THERAPY ASSOCIATION, New York

Occupational Therapy Exhibit of photographs, diagrams, charts and other means of demonstrating graphically a few of the methods of aiding the recovery of the sick by means of occupations of various kinds

NATIONAL BOARD OF MEDICAL EXAMINERS, Philadelphia

Exhibit of charts describing the work and progress of the National Board of Medical Examiners

AMERICAN PHYSIOTHERAPY ASSOCIATION

Modern Techniques in the Exercise Treatment of Faulty Body Mechanics Exhibit showing (1) methods of stimulating interest in body mechanics, (2) principles of progression in exercise treatment, (3) carry-over of principles learned in exercise treatment, (4) significant points in kinesiology of water activities, (5) methods of recording improvement in body mechanics, schematograph, silhouettegraph, (6) case records

AMERICAN ASSOCIATION OF MEDICAL SOCIAL WORKERS, Chicago

Contributions of Social Work to the Care of Ill Health Exhibit of (1) charts and graphs showing social factors in certain diagnostic groups, as (a) tuberculosis, (b) heart disease, (c) diabetes, (2) pamphlets and reprints of social studies

AMERICAN SOCIETY OF CLINICAL PATHOLOGISTS, Board of Registry

Training and Registration of Laboratory Technicians Exhibit of placards, signs and photographs illustrating the activities of the Board of Registry in regulating the training and standardization and registration of laboratory technicians in the United States, and a list of approved schools with pamphlets, booklets and other literature describing the work of the registry

CHILDREN'S BUREAU, U S Department of Labor, Washington, D C

Neonatal Mortality Studies of the Children's Bureau Exhibit of charts and maps dealing with neonatal mortality and related subjects, such as prematurity and neonatal morbidity

AMERICAN HEART ASSOCIATION, New York

Heart Disease as a Cause of Sudden Death Exhibit of charts and photographs of postmortem observations in sudden death, giving a summary of the lesions most commonly encountered in sudden, unexpected death from natural causes

Approximately 70 per cent of sudden deaths are due to organic heart disease and 90 per cent to lesions in the cardiovascular system (heart, arteries, arterioles, capillaries and veins)

COMMITTEE ON EVALUATION OF SERODIAGNOSTIC TESTS FOR SYPHILIS, AMERICAN SOCIETY OF CLINICAL PATHOLOGISTS AND THE UNITED STATES PUBLIC HEALTH SERVICE

Evaluation of Serodiagnostic Tests for Syphilis For description of exhibit see Symposium on Syphilis under Section on Dermatology and Syphilology

CHICAGO MUNICIPAL TUBERCULOSIS SANITARIUM, Chicago

Collapse Therapy in Pulmonary Tuberculosis For description of exhibit see Symposium on Tuberculosis under Section on Preventive and Industrial Medicine and Public Health.

AMERICAN MEDICAL ASSOCIATION

The exhibits from the headquarters group of the American Medical Association will be found in various parts of the hall. These exhibits are not open to awards

COUNCIL ON PHYSICAL THERAPY Exhibit of motion pictures illustrating physiologic effects of physical agents, demonstrations of useful therapeutic measures in the after treatment of fractures by physical therapeutic measures, charts and diagrams portraying results

COUNCIL ON PHARMACY AND CHEMISTRY Exhibit of posters, specimens and demonstrations showing the work of the Council on Pharmacy and Chemistry

CHEMICAL LABORATORY Exhibit of posters, specimens and demonstrations showing the activities of the A M A Chemical Laboratory, in its work for the Council on Pharmacy and Chemistry and the Bureau of Investigation.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS Exhibit showing the work of the Council in relation to 1 Resurvey of medical education 2 Postgraduate medical courses 3 Approved internships and residencies in specialties 4 Certification of specialists 5 Schools of laboratory technique, physical therapy and occupational therapy 6 Hospital statistics 7 Distribution of hospitals

BUREAU OF MEDICAL ECONOMICS Exhibit of charts showing numbers and percentages of physicians in active practice according to age, size of community and type of practice. Examples of forms that must be filled in for persons covered by the French compulsory sickness insurance system.

BUREAU OF LEGAL MEDICINE AND LEGISLATION Exhibit of posters on legal medicine and legislation.

AWARDS

There will be two classes of awards, consisting each of (a) a gold medal, (b) a silver medal, (c) a bronze medal and (d) three certificates of merit

[NOTE.—The special (subsidized) exhibits (diabetes, nutrition, vaccines and serums, and prevention of asphyxial deaths) and the exhibits of the headquarters of the American Medical Association are not open to awards]

CLASS I

Awards in class I are made for exhibits of individual investigations, which are judged on basis of originality and excellence of presentation

CLASS II

Awards in class II are made for exhibits that do not exemplify purely experimental studies, which are judged on basis of the excellence of correlating facts and excellence of presentation

Medals are awarded only to individuals. A special certificate of merit will be awarded to the best educational exhibit in the Educational Classification (this includes exhibits by national organizations)

The Committee on Awards will be composed of five persons. It will make the decisions on Wednesday, June 12.

The names of the members of the Committee on Awards will not be available until after the decisions have been published.

Each succeeding year has seen the technical exhibits at the A M A Convention take on more and more of an educational character. This year the Technical Exposition will reach a high point not only in number of exhibitors but in the quality of the exhibits themselves. They will represent practically every type of article or service needed by the physician in the practice of medicine. They will range all the way from small exhibits of single, highly specialized articles to motion pictures in separate projection rooms and a special showing of one of the most famous exhibits from the Chicago Century of Progress.

The vast size of the Atlantic City Auditorium will make the technical exhibits unusually convenient this year. These will be laid out on one floor along a uniform system of aisles and cross aisles. More important still, the scientific exhibits will also be located on the same floor, being merely separated from the Technical Exposition by a partition. Also all of the section meet-

ings and other sessions are to be accommodated in the Auditorium.

Visiting physicians will therefore find it unusually convenient to take full advantage of the Technical Exposition. Spare time before and after meetings each day can be spent with pleasure and profit by going about in a leisurely manner and getting acquainted with the firms represented, the products exhibited, and the men in charge. In each booth the physician will almost invariably meet one or more representatives well qualified to discuss the subject in which they are particularly interested.

The Exposition will be open from 8 30 a m to 6 p m each day. It will close Friday at noon. On the following pages will be found advance information as to what each individual firm will feature in its exhibit.

WILL C BRAUN,
Superintendent of Exhibits

APPARATUS AND INSTRUMENTS

Air-Way Surgical Belts

Speci-ally trained representatives of the Air-Way Surgical Company will be on hand in Booth 232 to give detailed information regarding their corrective garments on exhibition. These will include the Improved line of Air-Way Surgical Belts now embodying a new patented Pull and Uplift feature and also special surgical clasps and anchored laces.

Fine Wood Furniture

The W D Allison Company manufacturers of physicians fine wooden furniture for more than fifty years will display two new suites the Directoire and the Moderne—both practical and beautifully designed. Their popular Metropolitan suite and the new Improved Hanes reclot table will also be shown in Booths 102-103.

New Line of Furniture

In Booth 178 the A S Aloe Company will display for the first time to the medical profession the new Contempora line

of wood furniture in genuine American walnut at unusually low prices. In Booth 132 they will show their entire general line of instruments apparatus and equipment including the new style Elliott machine and Stille-Scanlon rustless steel instruments at a special discount of 25 per cent.

Portable Humidifiers

Portable humidifiers that evaporate approximately a pint and a half of water on hour and require only the equivalent of a 25-watt electric light bulb to operate will be exhibited by the American Gas Accumulator Company in Booth 216. If you are interested in humidifiers for home office or hospital use you are invited to pay special attention to this exhibit.

Bausch & Lomb Microscopes

You are invited to inspect the Model HA Physicians and Medical Students Microscope to be shown by the Bausch & Lomb Optical Co. in Booth 149. This instrument is superior for laboratory use because of its weight balance and stability. The exhibit will also include hemocytometers, colorimeters, micro-

Newest Baumanometer

The W A. Baum Company Booth 96 will have on display the latest of a distinguished line of Baumanometers—their new '100 Model'. Cased in Duralumin it is not only smaller in outside dimensions but actually roomier within. It carries the same exclusive Baumanometer guaranty of perpetual accuracy and against glass breakage as do all life-time Baumanometers. See this sturdy instrument.

Manufacturing Demonstrations

Becton Dickinson & Company will give two manufacturing demonstrations—one on the making of hypodermic syringes, the other on clinical thermometers. They will also show their new products including the B-D Dihalide Bakelite Pocket Case the B-D Venous Pressure Outfit with Luer-Lok connections Asepto Syringe with new Bakelite plug Improved Buser Automatic Injector and the three B-D Fever Thermometers devised for patients convenience. Booths 12, 43, 41, 45 and 46.

Betz Moderne Steel Furniture

The new Straight Line Steel Office Furniture in the Frank S. Betz Company's exhibit in Booth 117 will be well worth seeing. Also on display here will be the

A GLASS BLOWER SHOWS HOW FINE THERMOMETERS ARE MADE

new Betz Electric Centrifuges and a sample line of our surgical instruments equipment, supplies and specialties

Electrocardiographs

The exhibit in Booth 171 of the Cambridge Instrument Company Inc. pioneer manufacturers of electrocardiographs, will be of great interest to heart specialists who are invited to inspect the latest Mobile and Portable All-Electric Model Electrocardiographs and important accessories, and also a new portable Stethograph for amplifying and recording heart sounds. A combined Electrocardiograph-Stethograph will be demonstrated.

To Show Tele-Vaginalite

The latest developments in electrically lighted instruments will be exhibited by the Cameron Surgical Specialty Company in Booth 87. Included will be the Tele-Vaginalite (Micro-Colposcope), the new full vision, proximally lighted Bronchoscope and 5-in-1 Surgimold Ophthalmoscope, and also the Cameron Cauterodyne in a new and inexpensive model for cutting and coagulating in office and ambulatory surgery.

Castle to Show Sterilizers

In the Wilmett Castle Company's exhibit in Booth 188, will be displayed full automatic, cast-in bronze Castle Sterilizers, Castle Autoclaves for office clinics and hospitals, Castle Lights both major lights and spot lights, and the Humidifier which provides automatic humidity and temperature for infant care.

Respiration Apparatus

You are invited to inspect the very latest in respiration apparatus in Booth 74, where Warren E. Collins Inc. will exhibit the newest models of the Drinker-Collins Respirator. The improved Benedict-Roth Metabolism Apparatus will also be shown.

Sutures for Special Purposes

Dovis & Geck Inc. will show their complete line of sterile surgical sutures, including special purpose sutures with Atraumatic needles affixed for tonsil, thyroid, obstetrical, circumcision, plastic eye, ureteral and renal work. See the films from their Library of Surgical Motion Pictures to which many new subjects have been added since last year. Booth 129.

Skeletal Traction

If you are interested in fracture equipment see the DePuy Reducing Frame and Splint for lower leg fractures, and the special stainless steel Kirschner wire and Steinman pins which are guaranteed not to break. The DePuy Manufacturing Company will exhibit these in Booths 124 and 233.

DeVilbiss Nasal Guard

A prominent feature of the exhibit of the DeVilbiss Company, makers of medicinal atomizers will be the recently developed DeVilbiss Nasal Guard which prevents any excess pressure in the nasal passages during prescribed self-treatment. You are invited to inspect the complete DeVilbiss line of atomizers and vaporizers for both home and professional use, in Booth 101.

Innovations in Thermometers

The latest Elsie developments in syringes, needles and clinical thermometers will be on display in Booth 7. A representative of Elsie & Company will gladly show you the ingenious new needle lock for syringes and the new green pistons. The clinical thermometers will show innovations adding to their utility.

Recent Progress in Diagnosis

Many new features and developments that have taken place in electrically lighted instruments will be shown by the Electro Surgical Instrument Company in Booth 177. Do not fail to see the new Israel Bronchoscopes, the new Bute Proctoscope, the Branch Bumpus Resectoscope, the Russell Laryngoscope and Nongag Glottoscope and newer types of the Holmes Nasopharyngoscope and of Anthesopes and other instruments.

To Demonstrate Respirators

Because of the newly recognized importance of equipment for carrying patients through periods of impaired respiration physicians will find the J. H. Emerson exhibit of great interest. In Booth 35 they may see demonstrations of the standard Diaphragm Respirators and Oxygen Tent, and also of smaller instruments of definite interest to the practitioner.

Expert on Office Planning

The Enochs Manufacturing Co. will display a walnut suite of their popular Modern style treatment room equipment and some representative pieces of other matched suites. An expert on physicians office arrangement and decoration will be in attendance in Booth 68 to confer with doctors on any office planning problems.

A Stomach Camera

The Gastro-Phot, the tiny camera for direct photographing of the interior of the stomach will have its first showing by the Gastro Phot Laboratories in Booth 170. A large number of stomach photographs will be on display and competent men will be in attendance to give complete information regarding this ingenious instrument.

Walnut Table for General Use

The Hamilton Manufacturing Company will show a new walnut examining and treatment table with all the mechanical advantages of the best adjustable steel tables. The removable pan adjustable cushions, and top which can be raised in a horizontal position for examining and treating small children are features to be noted. Booths 149 and 141.

To Demonstrate Kinetometer

The Heidbrink Company pioneer in the field of anesthesia equipment designed for the carbon dioxide absorption method of anesthesia, has been distributing for the past year its latest improved equipment, the Kinetometer. This will be displayed and demonstrated in Booth 152 with other late models of oxygen therapy equipment.

New White Drybak Adhesive

In Booth 75 Johnson & Johnson will introduce a new white Drybak Adhesive Plaster as a companion to the well known sun-lan Drybak. The new white Drybak is soft and flexible, easy to apply and will not stiffen. Well informed representatives will be prepared to give interested physicians full information on Johnson & Johnson products.

New Keystone Telebinocular

Included among the new developments in orthoptic equipment to be shown by the Stereophthalmic Division of the Keystone View Company in Booth 76, will be office and clinic units, diagnostic units for home orthoptic training school and industrial vision survey units, maltingering tests, and complete standard anatomical stereograms.

Improved Traction Splint

In Booth 231, the Little Manufacturing Company makers of traction splints, will demonstrate an improved traction splint which definitely eliminates loss of traction and provides means for applying antero-posterior and lateral traction at any point desired. Mechanical means prevent the patient from getting the leg out of alignment and frequent adjustments are unnecessary. See it demonstrated!

Steel Surgical Instruments

In Booth 55 Charles Lentz & Sons, first makers of stainless steel surgical instruments in America, will show their NoCo Steel Cutting Instruments which retain a keen edge for hundreds of operations and which also defy the action of iodine, bi-chloride of mercury nitric acid lemon salt solution and other reagents used by physicians and surgeons

LENTZ NOCO STEEL**For Eye, Ear, Nose and Throat**

The ophthalmologist will be interested in the latest model training apparatus the Synoptophore, the new Hamblin Stereoscopic Charts and the Berens Ergograph, to be featured by the E. B. Meyrowitz Surgical Instruments Co. in Booth 85. Of great interest to the otolaryngologist will be the Rusklin Ear Set, the Watson Williams Set the Iodine Vaporizer, and a combination laryngeal mirror-spray

New Jones Motor-Basal

You may have your own metabolic rate shown in graphic form by the Middlewest Instrument Company, Booth 92. See the demonstration of the new All-Electric Jones Motor-Basal both hospital and portable models with inkless recording electric clock, waterless splanter and direct reading technic

New Bone Engines

Among the newer items in V. Mueller & Company's large display of surgical instruments and equipment in Booths 111 and 112, will be recent developments in both large and small bone engines the Furniss Intestinal Anastomosis Clamp, and new eye lamps by Dr. W. E. Shaban. The Wells' Iodine Vaporizer and DeBakey-Gillentine Blood Transfusion set will also be shown

**Modern Office Sterilizers**

In Booth 70 the Pellon & Crane Company will have a complete exhibit of modern office sterilizers, including the new Duplex Special model built-in type sterilizers, and the Pellon Automatic Autoclave for office use. You are also invited to inspect the new Pellon Indirect Flood Light, the new operating light with variable intensity and indirect illumination directly projected

See Instruments Demonstrated

Every doctor, regardless of his branch of medicine, will find a visit to Booth 54 worth while. Here representatives of the Penn Surgical Manufacturing Company, Inc., will be glad to demonstrate many new instruments and new apparatus without any obligation on the part of visitors

New Diagnostic Unit

The Philadelphia Surgical Instrument Company will exhibit in Booth 210 the new combination treatment and office diagnostic unit which provides suction and pressure pump, cautery and light transformers with the necessary cautery and light equipment and bottles and atomizers—all in one unit at an exceptionally low price

Sterilizers—Large and Small

A complete line of sterilizers from the small portable type to the heavy duty ward

**SUTURING TECHNIQS SHOWN IN MOVING PICTURES**

size all completely automatic in operation will be shown by the Prometheus Electric Corporation in Booth 28 and cabinet models in the new chip-proof enamel will be demonstrated. There will also be demonstrations of a small model food conveyor and of operating room lights of emergency and spot light types with many revolutionary features

New Thoracic Instruments

Specialists in eye ear nose and throat work in thoracic surgery and in bronchoscopy and esophagoscopy will find much of interest in the exhibit of George P. Pilling & Son Co. in Booth 114. The new thoracic instruments and both portable and stationary apparatus for pneumothorax together with bronchoscopic instruments identical with those used in the Chevalier Jackson Clinics will be on display

**Late Model Operating Table**

The latest model Scanlon-Balfour operating table A5a, which provides an extensive range of adjustments, the Operax Multi-beam equipped with swivel off-set assembly and the new type Scanlon-Morris high pressure water sterilizers will be features of the Scanlon-Morris Company's exhibit of surgical equipment in Booth 31. Scanlon heat sterilized surgical sutures will be demonstrated

**To Show Pivot Leg Splint**

Among the many new splints and future appliances shown by the J. R. Brandt Manufacturing Company will be the Pivot Leg Splint—the original rocking splint. Equipped with scale and traction, it assures a perfectly immobile fracture at all times, eliminates pain, muscle spasm and gives quicker red stop in at Booth 79 to inspect this

Prescribing Technic for L.

The Sight Light Corporation will demonstrate in Booth 250 of the prescribing technic developed for the thalimologist. Examine the simple ment recommended. See reports of suits obtained by following the of lighting established by the famous scientists in this field. Learn hand the facts about the contribution human welfare that improvement in conditions invariably produce

Pneumothorax Apparatus

Visit Booth 108 for a demonstration of the new portable and easy to use Davis Pneumothorax A

J. Sklar Manuf. also invites you to inspect line of suction and pumps, the new Ralks motic Blood Transfuser (illustrated), and a line of stainless steel chrome plated surgical instruments

New Perimeter for Oculists

In Booth 248 the J. E. Reid Instrument Company will show for the first time the Pascal Perimeter a new development of this type of instrument. You are invited to see it demonstrated as it is used in making both perimetric and campimetric examinations while the patient remains in the original position. Among other instruments of interest to the eye ear nose and throat specialists will be the May Ophthalmoscope with illuminated numerals

Metabolism Equipment

The Sanborn Company invites you to visit Booth 102 where the latest metabolism and electrocardiograph equipment will be exhibited. Be sure to stop in to see the new electric, inkless Sanborn Motor Graphic Metabolism Test, the new low priced Sanborn Electric-Portocardiograph with Redux the resistance-reducing electrode paste developed and perfected by Sanborn

Surgeons' Fine Gloves

Seamless Standard Surgeons' Gloves will be exhibited by the Seamless Rubber Company in Booth 106 where you may examine them and see for yourself how their anatomical shape greatly reduces finger fatigue. Also note how thin and tactile they are although they stand repeated sterilization without losing their life

Sonotone Hearing Aids

Sonotone 35 the latest hearing individual use developed by the Laboratories will be shown by the tone Corporation in Booth 126. are invited to note its improve previous models in volume

THE TECHNICAL EXPOSITION

A GLASS BLOWER SHOWS HOW FINE THERMOMETERS ARE MADE

Electrocardiographs
The exhibit in Booth 171 of the Cambridge Instrument Company, the pioneer manufacturer of electrocardiographs, will be of great interest to heart specialists who are invited to inspect the latest models and portable All-Electric Blind-Model series and also a new portable Stethograph for amplifying and recording heart sounds. A combined Electrocardiograph Stethograph will be demonstrated.

To Show Tele-Vaginalite
The latest developments in electrically lighted instruments will be exhibited by the Cameron Surgical Specialty Company in Booth 87. Included will be the Tele-Vaginalite (Micro-Colposcope) the new full vision, proximally lighted Bronchoscope and 5-in. 1 Surgimold Ophthalmoscope and also the Cameron Cauterodyne in a new and inexpensive model for cutting and coagulating in office and ambulatory surgery.

Castle to Show Sterilizers
In the Wilmet Castle Company's exhibit in Booth 108 will be displayed full automatic, cast-in-bronze Castle Sterilizers, Castle Autoclaves for offices, clinics and hospitals, Castle Lights both major lights and spot lights and the Humidifier which provides automatic humidity and temperature for infant care.

Respiration Apparatus
You are invited to inspect the very latest in respiration apparatus in Booth 34 where Warren J. Collins, Inc. will exhibit the newest models of the Drinker-Collins Respiration Apparatus. The Improved Benedict-Roth Metabolism Apparatus will also be shown.

Sutures for Special Purposes
Davis & Geck Inc. will show their complete line of sterile surgical sutures including special purpose sutures with Atraumatic needles adapted for tonsil, thyroid, eye, ureteral and renal work. The Atlas from their Library of Surgical Motion Pictures to which many new subjects have been added since last year. Booth 129

Skeletal Traction
If you are interested in fracture equipment see the DePuy Meducel Company and lower leg fractures, and the special stainless steel Kirschner wire and Stehman pins which are guaranteed not to break. The DePuy Manufacturing Company will exhibit these in Booths 124 and 233.

DeVilbiss Nasal Guard
A prominent feature of the exhibit of the DeVilbiss Company, makers of medical atomizers, will be the recently developed DeVilbiss Nasal Guard which prevents any excess pressure in the nasal passages during prescribed self-treatment. You are invited to inspect the complete DeVilbiss line of atomizers and vaporizers for both home and professional use in Booth 151.

Innovations in Thermometers
The latest Fiske developments in syringes, needles and efficient thermometers will be on display in Booth 7. A representative of Fiske & Company will gladly show you the ingenious new needle lock for syringes and the new green plastic. The efficient thermometers will show innovations adding to their utility.

Recent Progress in Diagnosis
Many new features and developments that have taken place in electrically lighted instruments will be shown by the Electro Surgical Instrument Company in Booth 177. Do not fail to see the new Israel Bronchoscope, the new Bule Proctoscope, the Bronsch-Bunnipus Resectoscope, the Russell Inforsyngoskop and Nongag Glottoskop and newer types of the Holmes Nasopharyngoscope and of Antroscopes and other instruments.

To Demonstrate Respirators
Because of the newly recognized importance of equipment for carrying patients through periods of impaired respiration, physicians will find the J H Emerson exhibit of great interest. In Booth 35 they may see demonstrations of the standard Murphyng Respirators and Oxygen Tent and also of smaller instruments of definite interest to the practitioner.

size all completely automatic in operation will be shown by the Prometheus Electric Corporation in Booth 26 and cabinet models in the new chip-proof enamel will be demonstrated. There will also be demonstrations of a small model food conveyor and of operating room lights of emergency and spot light types with many revolutionary features

New Thoracic Instruments

Specialists in eye ear nose and throat work, in thoracic surgery and in bronchoscopy and esophagoscopy will find much of interest in the exhibit of George P. Pilling & Son Co. in Booth 114. The new thoracic instruments and both portable and stationary apparatus for pneumothorax together with bronchoscopic instruments identical with those used in the Chevalier Jackson Clinics will be on display

New Perimeter for Oculists

In Booth 218 the J. E. Reid Instrument Company will show for the first time the Pascal Perimeter a new development of this type of instrument. You are invited to see it demonstrated as it is used in making both perimetric and campimetric examinations while the patient remains in the original position. Among other instruments of interest to the eye ear nose and throat specialists will be the May Ophthalmoscope with illuminated numerals

Metabolism Equipment

The Sanborn Company invites you to visit Booth 102 where the latest metabolism and electrocardiograph equipment will be exhibited. Be sure to stop in to see the new electric inkless Sanborn Motor-Graphic Metabolism Tester the new low priced Sanborn Electric-Portocardiograph with Redux the resistance-reducing electrode paste developed and perfected by Sanborn

Surgeons' Fine Gloves

Seamless Standard Surgeous Gloves will be exhibited by the Seamless Rubber Company in Booth 196, where you may examine them and see for yourself how their anatomical shape greatly reduces finger fatigue. Also note how thin and tactile they are, although they stand repeated sterilization without losing their life

Late Model Operating Table

The latest model Scanlon-Balfour operating table, A5a, which provides an extensive range of adjustments, the Operax Multi-beam equipped with swivel offset assembly and the new type Scanlon-Morris high pressure water sterilizers will be features of the Scanlon-Morris Company's exhibit of surgical equipment in Booth 31. Scanlon heat sterilized surgical sutures will be demonstrated

To Show Pivot Leg Splint

Among the many new splints and fracture appliances shown by the J. R. Siebrandt Manufacturing Company will be the Pivot Leg Splint—the original rocking leg splint. Equipped with scale and spring traction, it assures a perfectly immobilized fracture at all times eliminates pain and muscle spasm, and gives quicker reduction. Stop in at Booth 79 to inspect this splint.

Prescribing Technic for Light

The Sight Light Corporation will give a demonstration in Booth 250 of the light prescribing technic developed for the ophthalmologist. Examine the simple equipment recommended. See reports of the results obtained by following the principles of lighting established by the researches of famous scientists in this field. Learn firsthand the facts about the contributions to human welfare that improvement in seeing conditions invariably produce

Pneumothorax Apparatus

Visit Booth 108 for a demonstration of the new portable and easy to use Davidson's

Pneumothorax Apparatus. The J. Sklar Manufacturing Co. also invites you to inspect its line of suction and pressure pumps, the new Ralks' Automatic Blood Transfuser, Kane's Umbilical Clamp (illustrated), and a complete line of stainless steel and chrome plated American made surgical instruments

Sonotone Hearing Aids

Sonotone 35 the latest hearing aid for individual use developed by the Sonotone Laboratories, will be shown by the Sonotone Corporation in Booth 126. Visitors are invited to note its improvement over previous models in volume, clarity, natu-

ralness of reproduction and distance pick-up, as well as in size and appearance. Another advance to be shown is in the Lieber Oscillator, now available in high, medium and low pitch.

Suction and Pressure Outfits

For your inspection, C M Sorensen Company will have on display in Booth 71 several very interesting new models and combinations of Suction and Pressure Outfits, with their allied accessories for tonsil irrigation, coagulation and desiccation where these are indicated in the treatment of the ear, nose and throat

Scientific Optical Instruments

The Spencer Lens Company Booth 159 will show microscopes with the new low fine adjustment, and binoculars featuring the convenient converging inclinoculars. The Bright-Line Haemacytometers will be of particular interest. And other instruments on display will include new microscope lamps for research work, microtomes and photo micrographic cameras with side focussing telescope to insure easy and accurate focussing on the ground glass and plate

Desk Model Tycos

The Taylor Instrument Companies will feature their new desk model Tycos Sphygmomanometer finished in black and trimmed with chromium. You are invited to inspect this easily read thermometer which has no mercury to keep clean and which never requires testing. Booth 186

New Diagnostic Instruments

In Booth 12 will be a display of all the new developments in the diagnostic field originated by the Welch Allyn Company. It will include their ophthalmoscope with illuminated dial, new transilluminators, several new types of laryngoscopes, urethrosopes and Montague rectal instruments. Pitman pharyngoscopes, dilators and accessories, nasopharyngoscopes and retinoscopes

New Zeiss Equipment

In addition to their well known Microscopes, Photomicrographic and Projection accessories Carl Zeiss Inc., will exhibit a collection of Electro-Optical Instruments, such as Wolf-Schindler Flexible Gastroscope, Henning Oesophagoscope, and Laparo-Thoracoscope. Their display in Booth 142 will also include a new model Colposcope, ophthalmic instruments, Pulfrich Photometer, Refractometers and Polarimeters

Modern Fracture Equipment

The Zimmer Manufacturing Company's exhibit in Booth 81 will be headquarters for fracture apparatus of the most modern type. You are invited to inspect the bone instruments and reduction apparatus of latest design which will be on display

BOOKS

A M A Publications

In Booth 213 the American Medical Association will display its official periodicals and books, which you are invited to examine without any obligation. You are also welcome to stop at this booth and secure a catalog of the A.M.A. publications for future reference

MAKING GOOD USE OF A GOOD OPPORTUNITY

Important Revision of Osler

The forthcoming revision of Osler's Principles and Practice of Medicine by Thomas McCrae will be a feature of the D Appleton-Century Company exhibit in Booth 127. In addition to their standard line of medical literature they will show The Practitioner's Library of Medicine and Surgery, including the volumes on pediatrics and therapeutics just published and other new works of importance.

Blakiston's Publications

In the showing of their latest publications in Booth 117, P. Blakiston's Son & Company Inc. will direct attention to such new editions as Gould's "Medical Dictionary," Hughes-Gordon's "Practice of Medicine," Wolff's "Pathology of the Eye," Duke-Elder's "Refraction," Lawrence's "Diabetic Life," Springstun's "Doctors and Jurists" and "Recent Advance" volumes on Allergy, Endocrinology, Pathology, Ophthalmology, Neurology and Medicine

State Medical Journals

You are invited to visit Booth 213 where an electric display will point out the locations of the 32 official state medical journals which conform to the advertising standards of the American Medical Association. They are represented by the Cooperative Medical Advertising Bureau Chicago

"Cyclopedia of Medicine"

The newly completed "Cyclopedia of Medicine" in 12 large volumes and Desk Index will be an outstanding feature of the F. A. Davis Company's exhibit in Booth 50. "Clinical Tuberculosis" by Benjamin Goldberg and 33 other recognized authorities, Polevski's "The Heart Visible," new revised editions of Loewenberg's "Diagnostics of Internal Medicine" and Kennedy's "Practical Surgery of the Abdominal and Pelvic Regions," Dimmitt's new book on "Clinical Laboratory Methods," and many other works will be shown.

To Show Influence of HYGEIA

HYGEIA the Health Magazine, published by the American Medical Association for the layman will have an interesting exhibit in Booth 213 illustrating its influence in the home, the school, the library and the community. A series of HYGEIA articles will be shown on the screen to demonstrate to the visiting physicians how this magazine presents the point of view of the medical profession to the layman

Lea & Febiger Anniversary

In celebration of their 150th anniversary Lea & Febiger will show in Booth 109 'The American Journal of the Medical Sciences' published since 1820, and Gray's 'Anatomy,' published since 1859. Among their important new books shown will be Adair and Steigitz's 'Obstetric Medicine,' Clapp's 'Cataract,' Graham Singer and Ballou's 'Thoracic Surgery,' Duncan's 'Diabetes' and new editions of well known works.

Unusual New Books

In addition to new editions of well known texts and reference books the J. R. Lippincott Company exhibit will include such unusual new books as Pfaunder and Schlossmann's 'Diseases of Children,' Peham and Amreich's 'Operative Gynecology,' Kirschner and Ravdin's 'Operative Surgery,' Barker's 'Treatment of the Commoner Diseases,' Barborak's 'Treatment by Diet,' Goldthwait's 'Body Mechanics' and Moore's 'Principles of Ethics.' Booth 115

"Atlas Fundus Oculi"

One of the outstanding books of the year, Wilmer's 'Atlas Fundus Oculi' will be displayed by The Macmillan Company in Booth 107, where physicians are invited to examine it at their leisure. Also on display here will be Christie's 'Economic Problems of Medicine,' one of the most timely books of vital interest to every physician

Mosby to Feature Journals

Visitors are invited to make their headquarters at the C. V. Mosby Company's booth, No. 121, where their full line of medical journals will be shown. New medical volumes shown for the first time will include (radwols) 'Clinical Laboratory Methods and Diagnostics' new editions of 'Cloniding's 'Methods of Treatment,' Macleod's 'Physiology in Modern Medicine,' Sutton's 'Diseases of the Skin' and Pottenger's 'Tuberculosis in the Child and Adult'

ton's "Diseases of the Skin" and Pottenger's "Tuberculosis in the Child and Adult"

A FOOD EXHIBIT WHERE THE "TEST OF TASTE" IS ENCOURAGED

From the Oxford Press

Among the new books which the Oxford University Press invites you to inspect in Booth 84 will be: "X-Ray Interpretation" by Bull; fifth edition of "Applied Physiology" by Wright; "Diseases of the Chest" by Davidson; "Obstetric and Gynaecological Pathology" by Teacher; B.C.G. Vaccine by Irvine; "Head Injuries" by Rawling; and also the Oxford Loose Leaf Medicine and Oxford Monographs on Diagnosis and Treatment

New "Pediatrics" by Brennemann

At Booth 88 full particulars may be obtained regarding W. F. Prior Company's 4-volume loose-leaf set on pediatrics which will be ready for delivery in the early fall. "Practice of Pediatrics," edited by Joseph F. Brennemann, like Prior's other loose-leaf sets will be kept continually up to date by periodic additions and revisions

Saunders' New Books

W. B. Saunders Company in Booth 110, will show as part of their complete list of over 300 titles many new books and new editions. Of outstanding importance will be such new books as Hinman's "Urology," the 1935 Mayo Clinic Volume, Curtis' 3-volume work on "Obstetrics and Gynecology," Bickham's "Operative Surgery," Horrow and Sherwin's "Biochemistry," and Kitchens' entirely different kind of "Diagnosis."

"Surgery, Gynecology and Obstetrics"

The official journal of the American College of Surgeons is displayed by the Surgical Publishing Company in Booth 17, will include an extensive file of bound volumes. Visiting physicians and surgeons are invited to examine also the "International Abstract of Surgery," published as an integral part of "Surgery, Gynecology and Obstetrics," and "The Joy of Living," an autobiography of Dr. Franklin H. Martin, founder of the journal

Thomas' New Books

Charles C. Thomas Publisher, invites you to see these new books in Booth 169. Gay's "Agents of Disease and Host Resistance," Kanner's "Child Psychiatry," Steindler's "Mechanics of Normal and Pathological Locomotion in Man," Spurling's "Practical Neurological Diagnosis,"

Craig's "Amebiasis and Amebic Dysentery," Corlett's "Medicine Men of the American Indian," Wiener's "Blood Groups and Blood Transfusion," Haman's "Textbook of Surgery," 3rd Ed., and Hitchcock's "Physical Chemistry for Students of Biology and Medicine" 2nd Ed.

Showing Books in Preparation

All the latest publications of William Wood & Company and The Williams & Wilkins Company may be examined in Booth 187. Visitors can also secure advance information and examine specimen pages or sections of several important new textbooks now in preparation. Outstanding will be Beck's "Illustrated Obstetrics," Watson's "Gynecology," Harrison's "Radiogenology," and Best and Taylor's "Physiological Basis of Medical Practice."

DIETETIC SUPPLIES

Concentrated Beef Bouillon

Bovril, a highly concentrated beef extract combined with highly concentrated extract of fresh brewers' yeast will be demonstrated in Booth 23 by Bovril of America. Physicians may obtain descriptive literature concerning Bovril which has been prescribed by European physicians for nearly half a century and is accepted by the Committee on Foods

Strained Baby Foods

Harold H. Clapp, Inc. first to introduce commercially prepared baby foods to the medical profession and first to use enamel-lined containers for strained baby foods, will show their products in Booth 148. Representatives will be glad to discuss progress made in this field

Karo for Infant Feeding

Karo Syrup, Karo Powdered and U.S.P. Dextrose will be featured in Booth 122 by the Karo Products Refining Company. Physicians are cordially invited to visit this exhibit and get detailed information regarding the digestibility, energy value and composition of Karo, so widely used for infant feeding

To Serve Cocomalt Again

Cocomalt, the food concentrate that increases the food value of milk and supplies a Vitamin D content in a particularly

delicious form will be exhibited by the R. B. Davis Company in Booth 97 where the Director of the Home Economics Department will be in charge. You are invited to visit this exhibit and enjoy some delicious Cocomalt. Interesting scientific data will also be available.

For Prelacteal Feeding

To aid physicians calling on Booth 88, the Dry Milk Company will give a handy abstrical calendar. A staff of trained representatives will gladly furnish information concerning a successful prelacteal feeding procedure using Notional Beta Lactase the improved milk sugar. The new Special Dryca with added Vitamin B will be featured. Also exhibited will be Klim and Merrell-Saule Powdered Protein and Whole Lactate Acid Milk, as well as the Walker-Gordon Products and Barden Products

Dried Ripe Bananas

You are invited to visit Booth 67 and see the display of Food Concentrates, Inc., manufacturers of dried ripe bananas in Melatose products for the diets of normal infants and children and those suffering from chronic intestinal indigestion (celiac disease) and other intestinal disturbances. Literature and samples as well as information regarding Melatase will be available

Have a Cup of Sanka Coffee!

You are invited to have a cup of Sanka Coffee at the General Foods exhibit, Booth 27, and learn for yourself how good is this blend of the finest Central and South American coffees from which 97 per cent of the caffeine has been removed. If you register here you will receive a special gift package containing Sanka Coffee, D-Zerita Fast Bran products, and other foods of special interest to physicians

To Show Accepted Foods

In Booth 192, diagonally across the aisle from the A.M.A. booth General Mills, Inc. will display their products which have been awarded the seal of Acceptance of the Committee on Foods—Wheaties, Gold Medal "Kitchen Tested" Flour, Blisquick, and Softosilk Cake Flour

Gerber's New Process

In Booth 64 the Gerber Products Company will explain the new process of Shaker-Cooking of Gerber Strained Foods, a method by which the contents of the center of the can reach the temperature necessary for adequate sterilization in from one-fourth to one-third the time necessary by the usual canning procedure, resulting in a brighter color and better flavor of the foods. Booklets and reprints will be available, some for professional use same for distribution by physicians

To Serve Pineapple Juice

Those who are interested in pure fruit juices as an important part of the daily diet will be interested in the exhibit of Dale Pineapple Juice by the Hawaiian Pineapple Company, Ltd. at Booth 220 for a drink of natural golden juice of fresh, ripe pineapples and learn its value in the diet

Heinz Nutritional Charts

H J Heinz Company creators of the famous 57 Varieties of Pure Foods, will display their Strained Foods Tomato Juice and Breakfast Cereals especially suited to infant feeding and diet therapy. You are invited to register at Booth 137 for the Heinz Nutritional Charts a set of reference charts invaluable to the doctor in diet planning.

Display of Margarine

The Institute of American Fats and Oils invites you to visit Booth 245 and sample the delicious margarine made from domestic fats and oils. The Home Economics Director will explain its use instead of butter for the table and cooking and will distribute copies of the Institute's booklet "The Wholesomeness and Food Value of Margarine."

Irradiated Evaporated Milk

If you have questions regarding the irradiation of evaporated milk—concerning development potency uses etc.—a nutritionist of the Irradiated Evaporated Milk Institute will be present in Booth 212 to answer them. An irradiating machine shown in operation will be an interesting feature of this exhibit.

Motion Picture Auditorium

In Room 1 Mend Johnson and Company will show for the first time a number of interesting new motion pictures, including one on allergy and one on premature babies. Their products will be shown in Booths 184, 185, 214, and 215. One feature will be a series of photomicrographic studies of the porous Pabulum flake which is made possible by the thorough (patented) process of cooking.

To Serve Kaffee Hag Coffee

Doctors are invited to visit the Kellogg Company's booth number 72 for a cup of refreshing Kaffee Hag Coffee. Bottle exhibits showing the stages in decaffeinating coffee will be on display and the process explained. Kellogg's All-Bran will also be exhibited and reprints of articles dealing with research on bran and on caffeine will be available.

Preparation of Strained Vegetables

The Larsen Company packers of strained vegetables from the well known Green Bay Wisconsin district will have an exhibit in Booth 24. It will show a complete layout of the newest development in preparing strained vegetables—an all vacuum process which cooks strains and seals under vacuum to protect vitamins.

For Infant Feeding

Since the adjustment of the diet for babies deprived of human milk must always be of interest to physicians, the Mellin's Food Company will show the basic principles of Mellin's Food, with the sincere belief that evidence accumulated from long experience fully justifies the recognition of the value of Mellin's Food as a modifier of milk in infant feeding. Booth 116.

LOOKING INTO A MILK IRRADIATING MACHINE

A Completely Modified Milk

The M & R Dietetic Laboratories will have in their display Similac, a completely modified milk for infants deprived of breast feeding. Representatives will be on hand to explain the value of the low curd tension of Similac as it applies to infant feeding and also the special cases in which it has proved beneficial. They will also explain the value of Splintac, the powdered spinach, as a mineral supplement. Booth 125.

New Book on Infant Nutrition

Lactogen Hy-lac and Nestlé's Food will be displayed by Nestlé's Milk Products Inc. in Booth 190. A feature of this exhibit will be an attractive new book on Infant Nutrition, a copy of which will be available to every interested physician who visits the Nestlé booth.

The Story of Pet Milk

All physicians at the Convention are cordially invited to call at the Pet Milk exhibit Booths 193 and 194 where they may see through special material and interviews with representatives what the Pet Milk Company has learned about making evaporated milk in the fifty years since it founded the industry.

Tree-Ripened Fruit Juices in Cans

After years of research Dr P. Phillips Company has developed a process of canning tree-ripened, fully matured Orange Juice, Grapefruit Juice and Fonic Grapefruit Hearts and retaining to a high degree the vitamin C and other nutritional values of the fresh fruit. Visit Booth 49 and receive samples and information.

Calcium Derived from Milk

Weytone formerly called PMC, a dietary form of calcium entirely derived from milk, will be shown in its "new" package and new pleasant, odorless taste, in Booth 59. The Protein Mineral Company will have a visual display of the entire manufacturing process surrounding Weytone as it goes through a cheese manufacturing plant. Visitors may taste this unique form of calcium and thus test its pleasing palatability.

A Distinctive Carbohydrate

The Scientific Sugars Company, in Booth 217 will display Cytose, a carbohydrate

syrup for supplementing milk in infant feeding which has introduced a new standard of bacterial purity in infant nutrition. An interesting demonstration will be made of a new product which is expected to be ready for announcement at this time.

Smaco Carotene Products

The significant resemblance of S.M.A. to breast milk for infants deprived of that ideal food will be pointed out by the S.M.A. Corporation in Booth 82. The display will also include Smoco Carotene which may be used to provide Vitamin A activity in the same form in which it occurs in the natural human diet and uncomplicated by the presence of other vitamins.

New Strained Cereal

You are invited to visit Booth 128 and examine the new product which Stokely Brothers and Company have recently added to their line of Stokely Strained Foods. This is Stokely Strained Cereal specially prepared from farina rolled oats, wheat germ, barley flour, whole milk, soy bean flour, yellow corn meal, tricalcium phosphate and yeast.

Tomato Juice on Tap

Kemp's Sun-Ray'd Pure Tomato Juice will be dispensed free to thirsty doctors in Booth 175. The Sun-Ray'd Company will display a trophy won for the high quality Indiana tomatoes used, and will call attention to the patented process by which the juice is made to insure vitamin potency, non-separation, and smooth full-bodied flavor.

Have a Fresh Banana Drink

You may enjoy a variety of delicious drinks made from fresh ripe bananas before your very eyes. If you will stop at the United Fruit Company's exhibit Booths 160 and 161. Printed recipe cards for these banana drinks will be distributed. In addition, you may secure the latest scientific data on the nutritive and therapeutic value of the banana based on extensive research.

Value of California Prunes

Pamphlets and the latest literature containing full information on the nutritional

PHYSICIAN AND PHARMACEUTICAL MANUFACTURER DISCUSS THEIR COMMON PROBLEMS

and economic values of California prunes will be distributed in Booth 181 by the United Prune Growers of California. Much of the material in the pamphlets is based on the results of scientific research work completed during the past year and a half.

Feeding Test Animals on Display
Vitamin Food Company Inc. and Vegex Inc. will display in Booth 8 animals with feeding charts showing the results of various milk and growth factor from a new vitamin and other feeding combinations in winter feeding.

To Serve Vitamin D Milk
The Vitex Laboratories Booths 2, 3 and 4, will make and serve Vitex Vitamin D milk and will distribute reprints of clinical studies made with Vitex milks, and also of studies of Vitex Vitamin D milks in relation to dental caries control.

Steenbock Irradiation Process
All irradiated Vitamin D food and medicinal products produced by means of the Steenbock ultraviolet irradiation process will be displayed by the Wisconsin Alumni Research Foundation in Booth 211. In attendance will be highly trained scientists able to answer your questions with respect to the need for and efficacy of Vitamin D as well as matters relating to the Foundation's policies. Interesting educational literature based on extensive laboratory and clinical research may be had.

PHARMACEUTICALS AND BIOLOGICALS

Demonstrations at Abbott Booth
Technical, scientific demonstrations on local anesthetics, antiseptics, ephedrine and halibut oil will be given at the Abbott Laboratories Booth No. 77. These will show interesting physiological chemical and bacteriological action and facts which for the most part are not usually demonstrated except by trained technicians in a well equipped laboratory. Physicians are cordially invited to visit the booth and to ask questions.

Organotherapeutic Preparations
The sources of glandular preparations surgical ligatures, etc., in meat animals will be depicted at the Armour and Company Booth.

pany exhibit Booth 118 Pituitary thyroid and many other pharmaceuticals will be shown with the glands from which the substance is extracted. The exhibit will emphasize the necessity for proper handling of the highly perishable raw material from which organotherapeutic preparations are made. Competent men will be in attendance.

Possibilities of Dilaudid
At Booth 180 representatives of the Bilhuber-Knoll Corp. will be pleased to tell you about the morphine derivative Dilaudid, for the relief of pain and cough. Other products displayed will include Theocalcin, useful in the treatment of congestive heart failure and angina pectoris. Brobiturate sedative and hypnotic. Euresol for diseases of the skin and scalp, and Lenigallol for the various eczemas.

For Trigeminal Neuralgia
The Calco Chemical Company extend a cordial invitation to visit their technical exhibit, Booth 174. It will feature Trichlorethylene in a form that offers important features of convenience and protection in trigeminal neuralgia. Cinchophen (Calco) and Aminoacetic Acid (Calco) recently found to exert a significant effect upon urinary and muscle creatine in myasthenia gravis progressive muscular dystrophy and pseudohypertrophic muscular dystrophy.

Sodium Bicarbonate U S P
Church & Dwight Company who for 89 years have concentrated on producing pure sodium bicarbonate will exhibit in Booth 91 Here they will show those dependable old products that have stood the acid test of time since 1840—Arm & Hammer and Cow Brand Bicarbonate of Soda.

Pernicious Anemia Preparations
Chappel Bros Laboratories of Rockford Ill. will exhibit their different types of Liver Extract and show newest charts and research in treatment of pernicious anemia with parenteral liver extract. They will also show slides demonstrating blood con-

ditions in various types of anemia. Orders for professional samples and literature will be accepted at their Booth No. 48.

Visit Davies, Rose Exhibit
When rambling among the scientific and commercial exhibits you will find it pleasant and profitable to stop at the Davies & Co Booth No. 148. Here their representatives Messrs Mansfield Poole and Fleming will be happy to receive you and to explain the merits of the preparations displayed.

Dubin Aminophyllin
In Booth 176 the H. E. Dubin Laboratories will give daily demonstrations of the easy solubility of their product, Aminophyllin, so useful as a coronary vasodilator, myocardial stimulant and diuretic. Literature and complimentary samples will be available to interested physicians.

Latest Uses for Lipidol
A visit to the E. Fougere & Company Booth 139 will give you an excellent opportunity to acquaint yourself with the latest advances which have been made with Lipidol both from a diagnostic and therapeutic standpoint. Competent representatives will be in attendance.

Gilliland Biological Products
You are cordially invited to visit Booth 83 where the Gilliland Laboratories are displaying a complete assortment of biological products. The representative in the latest laboratory methods, as well as refined biologicals in which they specialize exclusively.

How Cod Liver Oil Is Concentrated
While s Cod Liver Oil Concentrate Tablets will describe their manufacture and show reprints of articles giving clinical evidence of the vitamin stability and accurate developments emphasizing the therapeutic value of the unsaponifiable portion of cod liver oil will also be presented.

Roche to Have New Display
The Hoffmann-La Roche preparations embodying the most recent advances in biochemistry and medicine will be featured in an entirely new exhibit constructed especially for this Convention. Among the favorites to be shown are Ellixir Alurate, Alurate Tablets and Sodium Alurate. Scientific men from headquarters at Nutley, N. J., will be present at Booth 94.

All About Mercurochrome
In Booth 33 Hynson Westcott & Dunning will emphasize the careful investigation and control which are behind their product Mercurochrome—the bacteriological standardization and pharmacological tests which are made as a final check. Competent members of the detail force will be in attendance.

Blood Chemistry Outfits
If you are interested in applying blood and urine chemistry to your routine work be sure to visit Booth 135 and learn about the simplified LaMotte Blood Chemistry Outfits. Chemists in charge will be glad to demonstrate the simplicity of the technique, to discuss the application of the tests and to explain the research and care which have been exercised in developing these outfits.

MR ALI MENTARY TRACT IS THE STAR PERFORMER IN THIS MOVIE

Ampoule Preparations

Their Council Accepted Ampoule preparations, particularly their ampoules of Dextrose (d Glucose) 50% Sodium Cacodylate and Calcium Chloride will be exhibited by Lakeside Laboratories, Inc. in Booth 74. Members of the research staff will be present to demonstrate the chemical, bacteriological and physiological methods used to insure the purity, sterility and safety of Lakeside products.

Lederle Exhibits

Staphylococcus Toxoid and its application in staphylococcal infections will be featured at Booth No. 143 by Lederle Laboratories, Inc. The use of Solution Liver Extract Paracenteral in pernicious anemia will be shown by charts and drawings. In addition a short moving picture will demonstrate the use of Liver Extract and give some high lights in the treatment of pneumonia. Other items will also be featured.

Dioramas at Lilly Booths

Departments of Eli Lilly Laboratories engaged in the production of Insulin (Insulin, Lilly), the Amylase, Extrallin, Merthiolate, Carborson etc., will be shown in three dimensions by six photographic dioramas. Among decorative features of the display will be life-size bas-reliefs of Aesculapius and Hygieia. Members of the medical staff will be in attendance to answer questions at Booths 99, 100 and 101.

Calceose and Creosote Therapy

The Moltle Chemical Company extend a cordial invitation to visit their Booth, No. 120. Here questions relative to Calceose and creosote therapy will be answered gladly. And, if you wish to leave your name and address, liberal samples will be mailed for clinical trial.

New Crystalline Vitamin C

At Booth 216 Merck & Co. will show for the first time their product Cehnone the new crystalline Vitamin C. There will also be a display of some actual chemical processes used in the manufacture of such medicinals as Iodine and quinine, and full-size charts in color of the central and autonomic nervous systems and their relationships to various organs. In conjunction with a display on Digtan there will be instructive charts designed to simplify the interpretation of electrocardiographs.

Cod Liver Oil Research

The Molline Company will demonstrate, in Booth 58, the various steps involved in the manufacture of Maltine with Cod Liver Oil, and will show evidence that the vitamin A value of cod liver oil is enhanced two-fold when administered as Molline with Cod Liver Oil. Charts and illuminated photographs will show results of recent laboratory research on this subject.

A New Topical Anesthetic

The exhibit of the Wm S. Merrell Company in Booth 93 will include a display of their new topical anesthetic Dithione. There will also be depicted in miniature settings two stages in the development of this pioneer pharmacocutaneous house. One is a reproduction of the early 19th century apothecary of Dr. Wm S. Merrell; the other is an interior view of the present day Merrell Biological Laboratory, where Merrell's Toxoids Typhoid Vaccine and Ithrogen Local are produced.

Antitoxins, Serums, Vaccines

A complete line of biological products will be shown by the Notional Drug Company in Booth 153. Methods of production and testing will be demonstrated. Among important products included in the exhibit will be Tetanus Toxoid, specific antigens for the prevention of hay fever treatment for Ivy and oak pollen. Leaflets will be furnished physicians to help awaken the public to the importance of immunization of young children against diphtheria, scarlet fever, smallpox and whooping cough.

Parke-Davis Accomplishments

A staff of expert technical men will be in charge of Booths 130 and 131 where Parke-Davis & Company will display a number of scientific accomplishments. These will include Meningococcus Antitoxin, a group of glandular products, the group of sedatives and hypnotics included in Ortol and other products of special interest to the medical profession.

"The Doctor" in Sculpticolor

The life-size sculpticolor "The Doctor" created for Petrologar Laboratories Century of Progress exhibit will be shown in Room 4 of the Convention Hall. This three-dimensional rendering of the famous Sir Luke Fildes' painting has attracted wide attention in 16 cities of the United States, where it has been viewed by four

million people in the past two years. The regular Petrologar pharmaceutical exhibit will occupy Booths 52 and 210.

Aminoacetic Acid Pure

The Pfanstiel Chemical Company in display Booth 251 will feature Aminoacetic Acid Pure (Glycine), for the treatment of muscular disorders, particularly myosthenia gravis and muscular dystrophy. Research chemicals, Pfanstiel, 39 rare sugars or related products and 30 amino acids or derivatives will also be displayed.

Puritan Maid Products

The Puritan Compressed Gas Corporation pioneer medical gas manufacturers will have on display in Booth 153 their own Puritan Maid brand of Nitrous Oxide, Ethylene Oxygen and Carbon Dioxide. They will also show the leading makes of oxygen tents, nasal catheter outfits and anesthetic apparatus which they distribute.

Toxicity of Bile Salts

The exhibit of Riedel-de Hoen, Inc. of New York will be devoted to such products as Decholin and Decholin-Sodium, Nostal (a mild but dependable hypnotic), and bile salts for experimental purposes. Also it will demonstrate the difference between chologogues and true cholericides and their respective toxicities. If you are interested in the increasing importance of liver detoxification in therapy don't miss Booth 195.

For Relief of Migraine

Gynergen, a product of the specific ergot alkaloid ergotamine, which has recently been shown to relieve migraine headaches, will be displayed by the Sandoz Chemical Works in Booth 120. Literature on the use of Gynergen in this condition, as well as in the prevention and treatment of uterine hemorrhage will be featured and discussed by competent representatives. Other products to be displayed are Scillaren-B, Calglucan, and Sandoptin.

Searle Research Products

G. D. Searle & Company will display several of the interesting products which have been developed in their Research Laboratories, the principal one of which is Aminophyllin (Searle). If you are interested in this new product for the treatment of cardiac disease you can get pertinent chemical information at the Searle Booth, No. 103. Other products which will be on display and demonstrated will be Sodium Morrhuate, Bismuth Sodium Tartrate and Chinofoin.

Pharmaceuticals Old and New

Shorp & Dohme will present an interesting display of their well-known pharmaceuticals and biologicals in Booths 60, 61, 62 and 63. Although no particular preparation will be featured, you will find at this exhibit a group of physicians and medical service men prepared to give special informative data concerning a number of important products, old and new.

To Show New Vaso-Constrictor

Benzedrine (benzyl methyl carbinamine), a new vaso-constrictor indicated for shrinking the nasal mucosa in head colds, sinusitis, vasomotor rhinitis, hay fever and asthma will be exhibited by Smith, Kline and French Laboratories. Samples of the product and literature on its chemical structure and use can be had of Booth 85.

SATURDAY, MAY 11, 1935

THE ATLANTIC CITY SESSION

Elsewhere in this issue appear the announcements associated with the annual session of the American Medical Association, which will be held in Atlantic City, June 10-14. For the first time in history there is a joint session with the Canadian Medical Association. Atlantic City offers marvelous opportunities for a session held under the best possible physical conditions as to hotels and meeting places, for recreation in a salubrious atmosphere, and for entertainment surpassing that available in most other seaside resorts.

Attention is called here particularly to the scope of the scientific and technical exhibits at the Atlantic City session. Both in quantity and in quality of material they represent a new level in such educational features. The General Scientific Meetings have been planned as a graduate course for general practitioners of medicine in some of the problems of most immediate concern.

The Opening General Meeting introduces a notable speaker in the person of Hon. Walter Edge and addresses by the presidents of the Canadian and American Medical Associations on the physiology of respiration and our present knowledge of nutrition in relationship to the future of man. Among the list of our foreign guests from London are Mr. Leslie Paton, Mr. Norman Patterson and Sir Francis Shipway.

It is impossible in the scope of an editorial even to begin to emphasize some of the exciting and extraordinary contributions in the programs of the various sections. More than 350 separate contributions cover every aspect of modern scientific medicine. Attention should be called specifically, however, to the program of the surgical section, which on this occasion is particularly designed to cover the relationship of physiology to the advancement in surgery as a specialty and will provide a review of our knowledge of the blood and of immunology along entirely new lines. The Section on Pathology and Physiology has moreover provided a special program by the founders of the section, including Drs. Ludvig Hektoen, Walter L. Bierring, James B. Herrick, George Blumer and Simon

Flexner, who will present a survey of advancement since 1900 in various medical fields depending on pathology. Attention is called also to the sessions on anesthesia, military medicine and the history of medicine, which are special features of this joint meeting.

In the Scientific Exhibit, collective exhibits of recent research on chronic arthritis, tuberculosis, syphilis, cancer, infections of the central nervous system, vaccines and serums and many other subjects afford extraordinary opportunities for rapidly bringing the physician up to date in these fields.

The indications are that the attendance at the Atlantic City session will rival that of the largest medical meetings ever held elsewhere. Arrangements are being completed for several national broadcasts from the meeting. Those who plan to attend should make hotel reservations¹ at the earliest possible moment, to be assured of comfortable accommodations near the centers of interest.

CALIFORNIA HEALTH INSURANCE BILL

Space is not available in these editorial columns for a complete analysis of the proposed California health insurance act, which has been made by the Bureau of Legal Medicine and Legislation. However, a brief review of the proposed legislation and its method of development calls to mind a statement made by Justice Stephen of the High Court of Justice, Queen's Bench Division, in Great Britain, who said, many years ago,

I have had on many occasions to draft Acts of Parliament, which, although they may be easy to understand, people continually try to misunderstand, and in which, therefore, it is not enough to attain to a degree of precision which a person reading in good faith can understand, but it is necessary to attain, if possible, to a degree of precision which a person reading in bad faith cannot misunderstand. It is all the better if he cannot pretend to misunderstand it.

As was emphasized in *THE JOURNAL* last week, the proposed California health insurance act is presumably a creation of the committee of six of the California State Medical Society, which is using intense efforts to put the medical profession solidly behind the legislation, and of the interim committee of the senate, appointed two years ago, which has functioned largely through Mr. Celestine Sullivan.

An analysis of the act indicates that the system it will set up can hardly be called an insurance system, since benefits and the costs are not distributed in proportion to the risks of the contributors. The act yields no evidence of any attempt to lessen the total cost of illness or injury. It does, however, definitely add to the ordinary cost of illness the expenses of an elaborate administrative system, which must be paid before contributors to the fund receive any benefit whatever. It taxes all employees subject to the act 3.5 per cent of their wages and all employers 1.5 per cent of the wages paid to such employees, but the contributing employee

¹ For list of hotels, see page 1719 and advertising page 115.

receives no benefits unless he or some of his dependents become ill or injured or pregnant, except for children under 14, who are entitled to some medical supervision. No matter how long or how much an employee pays, his payments have no withdrawal or cash value. It should be obvious, moreover, that employers in many instances will add the amount of the tax to the price of the services or goods sold or offset the tax by lessening the wages of the employee. There is a special clause in the bill which completely frees the state of California itself from any liability in excess of the resources of the fund created by this legislation.

Concerning the benefits promised and attractively set forth in this legislation, not one of them is guaranteed, because all may be shortened and reduced by the health insurance commission, which commission, incidentally, contains two doctors and three laymen. A definite limit of twenty-six weeks is set up in relationship to any one illness or injury, a limitation that will throw the worker on his own resources at the time when help is most needed, as in cases of cancer, diabetes, heart disease, infantile paralysis or other prolonged diseases or injuries. Under this proposed act dental service is to be had in the vast majority of cases only on prescription of a physician as therapeutic dental service. The additional benefits mentioned under the bill which involve nursing service outside a hospital, exceptional drugs and medicines, institutional convalescent care and necessary dentistry, are to be had only in case the amount of money in the health insurance fund justifies the expense, and this is to be determined by the commission that administers the fund.

Probably most of the population of California will be compelled by this act to pay for the benefits it offers them whether they use the benefits or not, and there is no provision for rebate in case they fail to avail themselves of these benefits. Free choice of physician is not offered, because the patient can get the benefits of the act only if he uses the services of a doctor practicing under the act. Something is said as to the patient's right to choose his own physician, but the commission may at any time for cause strike the name of a doctor off the available list. Such a set up will inevitably tend to lower the number of physicians engaging in the private practice of medicine and to handicap them definitely by forcing their patronage into the system.

Nothing has been found in a thorough search of this bill that gives the slightest clue as to the manner in which physicians, dentists, hospitals, nurses and pharmacists are to be paid. Apparently the commission itself will rule as to whether payment will be made by fee or salary and as to the amount of such payments. There is nothing in the act that insures to the physician a fair voice in determining the conditions of payment. Not a word is said as to hours of service, postgraduate study, vacations, equipment, supplies, the number of patients any one physician or dentist will be allowed to treat, the reports that he may be required to make,

or any of the other details that will determine whether or not the proposed system maintains the standard of medical service in California. In order to render service under any health service insurance association the doctor must obtain a license from the commission and renew it annually. In order to get a license he must furnish the commission with a great deal of personal information about himself and his affairs. He must pay a minimum fee of \$5 and file a bond not to exceed \$25,000 to guarantee his activities to the commission. Moreover, hospitals, dentists, nurses and pharmacists are likewise in every sense of the word the slaves of the health insurance commission.

It is amusing in considering the drafting of this legislation to realize that the commission is to be composed of five members, "all of whom shall have been residents of California for at least a total of ten years." This is mentioned particularly, because this may mean that all five members are to have had ten years of residence in California or that each member is to have had ten years of residence in California. Aside from these qualifications, the act specifies no qualification of any commissioner except that he cannot hold any position of trust or profit and engage in any business, occupation or profession the duties of which are inconsistent with his duties as a commissioner. This would no doubt bar any physician who wished to continue in practice but might not interfere with other members, who could continue their usual occupations.

Every effort seems to have been made in drafting this act to give the commission authority as nearly absolute as is possible under our form of government and to protect it in every possible way from any control by the courts of the state of California.

The proposed California insurance act has been studied by several competent men of both legal and medical training. All are agreed that the draft is in such a form as to render intelligent analysis extremely difficult. Certainly it is not in a form that will permit proper consideration and action by any legislative body. There is no adequate provision to keep the administration of the act out of politics. There is nothing to assure a nonpartisan commission from the political point of view. It seems evident that the personnel of the commission and its employees and the amount of money involved are greater than may be concerned in any other activity in the state of California. There is nothing in the act to show that it will improve the quality of medical service or lessen its cost, but there is plenty of evidence to indicate that the expense of administration will add greatly to the cost of service.

As was stated previously, space is not available here for a complete and detailed analysis of this proposed legislation. Indeed, the only reason for giving it consideration is the example it sets to other states in relationship to this work. In California apparently the medical profession, as represented by its elected officials,

has had rather large opportunity to express itself in the drafting of the legislation. Yet even with this opportunity the legislation proposed is complex, inadequate and dangerous. How much less is the likelihood of decent legislation from the point of view of the medical profession and the public health in states in which the medical profession may not have opportunity to express its point of view?

OSTEOPATHY IN GREAT BRITAIN

Many of our readers have no doubt observed in the London letter a discussion of the hearings on osteopathy before a select committee of the house of lords in the British parliament. The attempt to obtain state recognition for osteopathy in Great Britain came "to an ignominious conclusion," in the words of the London *Lancet*, when on April 12 the leading counsel for the promoters of the bill announced the decision of his clients to proceed no further with it. The reasons given for withdrawal were two. It was said that during the course of the meetings the issue had changed. "It was now not so much the desirability of the registration of the osteopaths and the regulation of the practice of osteopathy as the question whether osteopathy could be said to rest upon a scientific basis." The second reason for the withdrawal was the position of the British School of Osteopathy.

Since it was clear to the opposition to this bill that the proponents had gotten themselves into a difficult spot, the opposition objected to the suggestion to discontinue the hearings, but the committee ruled that it would hear two more witnesses and then discontinue. The proponents of the measure threw overboard any defense of the seven bulletins of the A. T. Still Institute for Research. The *British Medical Journal*, in its consideration of the situation, says "When the reputable osteopaths have established an osteopathic school in this country with even a semblance of efficiency, have associated therewith a hospital (not merely an outpatient clinic) of reasonable size, have passed a number of students through their full course at such school or hospital, and have satisfied some scientific body that they have some prima facie evidence which can be submitted for examination, then, and then only, there may be a case for further official action on behalf of the community."

The inquiry by parliament into osteopathy occupied a good many days and cost a lot of money. It brought out the fact that the proponents of the legislation were not capable of framing a definition of osteopathy that would distinguish it from other healing cults. It made clear the fact that the osteopaths claim that their art and practice cover the whole field of medicine and that osteopathy is based on a pathology and a theory of causation which are peculiar and in no sense of the word established. Although the osteopaths were willing

to accept certain limitations on their work and to stress spinal manipulation, they claimed the right to use surgery of all degrees and drugs of many varieties. Indeed, they claimed equally to prevent disease by spinal manipulation and to limit infectious disease by this process.

In contrasting conditions between Great Britain and the United States, the *British Medical Journal* says

The legal position as to the practice of healing is radically different in this country from that which exists in the United States of America. There all such practice is forbidden except to those who are registered here, with a very few minor exceptions, it is open to anybody. In America, therefore, registration and regulation are necessary to enable people to choose whatever kind of attention they desire. Here there is no such necessity. In this country the state, while allowing this liberty, has established a single Medical Register, mainly to prescribe a minimum standard for practitioners who may properly have certain duties imposed upon them and be used by the state officially for the advantage of public health. It follows from this system that the consequences of state recognition of more than one register would be given an authoritative cachet to perhaps inconsistent theories and practices, and must lead to a very difficult, almost impossible, position in public health administration.

This consideration should emphasize to every intelligent person the necessity for developing in the United States, through the establishment of basic science laws, a minimum standard of education for all who propose to heal the sick, regardless of the method by which such healing is to be brought about. Great Britain seems to have realized the value of its own method of control. Apparently it still requires some extensive education of both legislators and the American people to bring them to a realization of the necessity for basic science legislation in this country.

Current Comment

EARLY DOCTORS IN ATLANTIC CITY

For many years the Jersey coast has been recognized as a region of great healthfulness. In the seventeenth century Gabriel Thomas, according to some items discovered by Dr. Philip Marvel, wrote to a friend saying "Of doctors and lawyers I shall say nothing as this country is very peaceful and healthy." Later on Dr. John Gordon, writing to his brother in England, said "If you design to come hither sometime, come as a planter or merchant, but as a doctor I cannot advise you, as I hear of no diseases to cure, but some agues and cut fingers, and legs." Among the pioneers in Atlantic City was Jonathan Pitney, who settled at Absecon in 1819 and called attention to the cleanliness of the sand dunes, the absence of mud and the purity of the air. The need of facilities for transportation led to the formation of a committee, on which Dr. Pitney was included. Through the efforts of this committee the first system of railroad transportation covering the sixty miles from Philadelphia to Atlantic City was built some eighty-five years ago.

BLINDNESS, CHRISTIAN SCIENCE AND SENATOR COPELAND

"The Senate proceeded to consider the bill (S 2153) to provide for the prevention of blindness in infants born in the District of Columbia

"Mr Copeland Mr President, there is an amendment on the desk of the clerk which I desire to suggest to the bill

"The President *pro tempore* The clerk will state the amendment

"The Chief Clerk On page 3, line 15, after the word 'physician' and the period it is proposed to insert the following

The provisions of this act shall not be construed to apply to persons treating human ailments by prayer or spiritual means as an exercise or enjoyment of religious freedom

"The President *pro tempore* The question is on agreeing to the amendment.

"The amendment was agreed to

"The bill was ordered to be engrossed for a third reading, read the third time, and passed" *Congressional Record*, April 15, 1935, pp 5860-5861

And so the Senate of the United States, on the motion of the Senator from New York, Royal S Copeland, a doctor of medicine and at one time commissioner of health of the city of New York, recognized "prayer or spiritual means" as legally sufficient protection against ophthalmia and blindness in new-born babies

Association News

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45 Chicago daylight saving time (3 30 p m central standard time) The next three broadcasts will be delivered by Dr W W Bauer The titles will be as follows

May 16 Children's Eyes
May 23 Saving Our Eyesight.
May 30 Eye Accident Prevention

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4 15 Chicago daylight saving time (3 p m central standard time) The next three broadcasts will be as follows

May 14 Training Good Doctors W D Cutter, M D
May 21 Pain W W Bauer M D
May 28 Problems of American Medicine Morris Fishbein M D

Broadcast, May 11, in Commemoration of National Hospital Day

The American Medical Association, through the courtesy of the Columbia Broadcasting System, will broadcast on a nationwide network on the afternoon of May 11 at 4 o'clock eastern daylight saving time (3 p m eastern standard time, 2 p m central standard time, 1 p m mountain time 12 noon Pacific time) in commemoration of National Hospital Day, which falls on May 12

Speakers will be Dr Howard W Haggard of Yale who will speak on Hospitals of Yesterday, and Dr Charles Gordon Heyd, past president of the Medical Society of New York, who will speak on Hospitals of Today The program will be introduced from Chicago by Dr W W Bauer Drs Haggard and Heyd will speak from the Columbia Broadcasting System Studios in New York.

CONNECTICUT

Public Health Meeting—The Connecticut Public Health Association will hold its annual meeting in Bristol, May 15 Following an address by Dr Stanley H Osborn, state health commissioner, on "Highlights of Health Legislation," there will be a symposium on pneumonia by Drs Roderick Heffron, Boston, John A Wentworth, Hartford, and Millard Knowlton, Hartford. The afternoon will be devoted to a symposium on school health service Speakers will include Dr Reginald M Atwater, New York, executive secretary, American Public Health Association, Dr Charles C. Wilson, Hartford, director of health and physical education of the board of education, Wilson S Dakin, supervisor, rural education, state board of education, Miss Helen Brundage, R.N., school nurse for Brookfield, New Fairfield, Sherman and Weston, and Karl Reiche, superintendent of schools, Bristol

DISTRICT OF COLUMBIA

Medical Society Protests Proposed Huge Medical Center—The establishment of a medical center in the District of Columbia, to replace the present hospitalization system, was opposed by the Medical Society of the District of Columbia in a nine page report adopted April 17 Under the plan which was submitted early in April by Commissioner George E Allen,

all existing hospital facilities would be united. In addition, one large hospital would be constructed at a cost of more than \$5,000,000 from public works funds as a self-liquidating project and would be operated on a nonprofit basis. The society averred in its statement that an endowment of from \$50,000,000 to \$100,000,000 would be necessary to maintain the proposed center, in excess of the contemplated cost and asked the commissioners' committee to name the promoters of the project and the form of guaranty they offer the public and the medical profession that they are able to carry the plan through. The report was drawn up by the committee on medical economics of the society.

FLORIDA

Bills Introduced—Committee Substitute for S 142 proposes to require every licensed physician, chiropractor, naturopath or midwife (1) to register his license with the clerk of the circuit court of the county in which he practices and (2) to register with the state board of health, on or before January 1, and to pay a fee of \$2. If a practitioner subsequently changes his residence or changes the place in which he practices he must reregister with the state board of health and pay a fee of \$2. H 748 proposes to require all hospitals maintained wholly or partially by public funds to permit any licensed practitioner of the healing art to practice within their confines. H 816 proposes to authorize all persons licensed to practice any form of the healing art to make examinations and issue certificates showing the condition of health of all persons required by any law to be examined for any purpose whatever.

State Medical Meeting at Ocala—The sixty-second annual meeting of the Florida Medical Association will be held at Ocala, May 13-15, with headquarters at the Marion Hotel and under the presidency of Dr. Homer L. Pearson, Miami. The following program has been arranged:

Dr. Herbert R. Mills, Tampa: *Friedman Test for Pregnancy: Report of Two Hundred Cases*
 Dr. Samuel R. Norris, Jacksonville: *Obstetric Liabilities*
 Dr. Henry Hanson, Jacksonville: *Maternal Mortality*
 Dr. Pearson, Miami: *The Physician and His Government*
 Dr. James E. Paulin, Atlanta, Ga.: *Arthritis*
 Dr. Chadbourne A. Andrews, Tampa: *Diagnosis and Management of Skin Diseases*
 Dr. Shaler A. Richardson, Jacksonville: *The Care of Cataract Patients*
 Dr. Lawrence C. Ingram, Orlando: *The Tonsil Problem*
 Dr. Emory W. Bittzer, Tampa: *Observations on the Mechanism and Treatment of Circulatory Failure*
 Dr. John R. Chappell, Orlando: *Boils and Carbuncles*
 Dr. Thomas O. Otto, Jr., Miami: *Principles of Plastic Surgery of Benefit to the General Surgeon*
 Dr. Walter C. Payne, Pensacola: *Infections and Treatment of Cervix Uteri*
 Dr. Warren W. Quillian, Coral Gables: *Immunization Against Contagious Diseases of Childhood*

At the annual dinner Tuesday evening Dr. Henry C. Dozier, Ocala, will be toastmaster, and Dr. Stewart R. Roberts, Atlanta, the speaker. The woman's auxiliary will meet Monday and Tuesday. Other associations meeting at this time include the Florida Railway Surgeons Association, the Florida Radiological Society and the Florida Society of Dermatology and Syphilology.

ILLINOIS

Bills Introduced—S 363 proposes to enact a new chiroprody practice act. It proposes to permit a chiroprodist, by any means or methods, to diagnose, recommend or prescribe for any ailment or supposed ailment of the human foot by local medical, mechanical or surgical treatment, including general manipulative massage, whether manual, mechanical or electrical. A chiroprodist is not to amputate the foot or toes, use anesthetics other than local, or use drugs or medicines other than local anesthetics. S 408 proposes to prohibit the manufacture of cosmetics, medicines or drugs without a license from the department of agriculture and the payment of a fee of \$2,500. The department is to investigate the contents and ingredients of the cosmetics, drugs or medicines manufactured by the person applying for a license, and, if it finds that the articles are adulterated or that any statement in the application is false or misleading or that the brand, name or any label or advertisement of the product gives a false indication of origin, character, composition or place of manufacture, it may refuse to license the applicant. H 937 proposes a system of compulsory and voluntary sickness insurance. The benefits proposed consist of cash and all forms of medical and dental service. Persons employed at other than manual labor and receiving wages in excess of \$60 a week, farm laborers and persons employed by an employer having less than three employees in personal or domestic services, are excluded from the compulsory insurance of the bill but are entitled to participate in the voluntary insurance.

CHICAGO

Grant for Research on Phenolphthalein—Phenolphthalein Research, Inc., is an organization of manufacturers and those interested in the distribution of phenolphthalein to develop facts regarding this drug. The research will be carried out under a grant to the University of Illinois College of Medicine and in other institutions.

Rise in Birth Rate—There were 47,850 births reported in Chicago in 1934 as compared with 46,655 in 1933, according to the *Chicago Tribune*. This is the first year since 1898 it was stated that the birth rate has increased over the previous year. The report points out that the birth rate of 13 per thousand of population recorded in 1933 was just half of the rate (26 per thousand) in 1904.

INDIANA

Roentgen Society Disapproves of Tuberculosis Survey—At a recent meeting of the Indiana Roentgen Society, a resolution was adopted declaring that general tuberculosis surveys are in their nature mass production and therefore inefficient and create a sense of false security and tend toward socialized medicine. This action was taken following a recent request for and discussion of a general tuberculosis survey of school children. The society recommends scientific examination by competent physicians and qualified roentgenologists rather than mass production methods. The society believes that since a negative roentgen examination may be followed in three months by a positive one, the surveys are of questionable value unless repeated at frequent intervals, in that they create a sense of false security in the minds of parents and occasionally a loss of valuable time while the disease remains unrecognized.

MARYLAND

State Medical Meeting and Election—Dr. Frederick D. Chappelcar, Hughesville, was elected president of the Medical and Surgical Faculty of Maryland at its one hundred and thirty-seventh annual meeting in Baltimore, April 23-24, to succeed Dr. John M. T. Finney, Baltimore. Other officers are Drs. Harvey G. Beck, Baltimore; Jesse O. Purvis, Annapolis, and Norman S. Dudley, Church Hill, vice presidents; Dr. Walter Dent Wise, Baltimore, secretary, and Dr. Joseph Albert Chatard, Baltimore, treasurer, to fill the unexpired term of the late Dr. Charles E. Brack. The new officers will be installed next January. The Trimble lectures were delivered at this meeting by Dr. Leonard G. Rowntree, Philadelphia, on "Further Studies on the Thymus and Pineal Glands," and Victor G. Heiser, New York, "The Need for Research in the Prevention of Surgical Diseases." Other speakers on the program were Dr. Olin West, Secretary and General Manager of the American Medical Association, Dr. Finney, on "The Acute Abdomen," and Drs. Wise, Harvey B. Stone and Maurice C. Pincoffs, who participated in an open forum on present-day medical trends. Table clinics and a round table luncheon also formed a part of the program.

MASSACHUSETTS

Bill Introduced—S 484 proposes to authorize the establishment in the town of Norfolk of a hospital for the confinement and care of the criminal insane.

Personal—Dr. Frederick F. Russell, general director, International Health Division, Rockefeller Foundation, has been appointed lecturer on preventive medicine and hygiene and epidemiology, Harvard Medical School, for one year beginning in September. The *Boston Herald* announces the retirement of Dr. Harriet E. P. Vaughan as a missionary in India. Dr. Vaughan began her service in 1895 under the American Board of Commissioners for Foreign Missions. Dr. Arthur N. Ball, assistant to the commissioner of mental diseases, has been appointed superintendent of the Northampton State Hospital, Northampton, succeeding the late Dr. Edward W. Whitney.

Meeting of Obstetricians and Gynecologists—The spring meeting of the New England Obstetrical and Gynecological Society was held in Springfield, May 1. Clinics occupied the morning and in the afternoon the following papers were presented:

Dr. Oliver J. Menard: *The Thyroid in Pregnancy*
 Dr. Paul M. Ashton: *A Comparison of Results of the Classical and the Low Cervical Cesarean Section*
 Dr. Rafe Nelson: *Hatt Congenital Deformities and Birth Injuries*
 Dr. Stanley S. Stusick: *The Problems of the Cystocele*
 Dr. Norman A. Tokorn: *Medical Diseases of the New Born*
 Dr. Walter W. Williams: *Morphologic Characteristics of Spermatozoa as a Means of Estimating Functional Possibilities*

All the speakers are Springfield physicians.

MISSISSIPPI

State Medical Meeting at Biloxi—The Mississippi State Medical Association will meet in Biloxi, May 14-16, with headquarters at the Buena Vista Hotel and under the presidency of Dr. Edward C. Parker, Gulfport. A general open session will be held Tuesday evening, May 14, at which Dr. Parker will deliver his official address on "Highway Accidents in Mississippi," and the Ewing Fox Howard Oration will be delivered by Dr. Giles S. Bryan, Amory, on "The Universal Challenge." Guest speakers from outside the state will be

Dr. Seale Harris, Birmingham, Ala., Dietary Management of Diabetes Mellitus—Hypoinsulinism and Hyperinsulinism
Dr. William Thornwall Davis, Washington, D. C., Asthenopia and Headache Not of Ocular Origin (Differential Diagnosis)
Dr. Robert E. Parrish, San Antonio, Texas, Mastoid Complications
Dr. Charles F. Craig, New Orleans, Prevention and Control of Amebiasis
Dr. Charles A. Thomas, Tucson, Ariz., The Collapse Program in Pulmonary Tuberculosis

A round table discussion will be conducted during a boat trip Wednesday afternoon, May 15, by Dr. Davis, on strabismus, and Dr. Parrish, on further mastoid complications. Among Mississippi physicians who will participate in the program will be the following:

Dr. William A. Dearman, Gulfport, Pulmonary Moniliasis
Dr. William K. Purks, Vicksburg, Electrocardiographic Diagnosis of Coronary Occlusion
Dr. Robin Harris, Jackson, Foreign Bodies in the Food and Air Passages
Dr. Leon C. Davis, Greenville, Etiology and Significance of Mydriasis
Dr. William D. Hickerson, Natchez, Diagnostic Clinics as Aids in Preventing Tuberculosis
Dr. David A. Ratliff, Columbia, Management of Labor in the Home
Dr. Reuben B. Caldwell, Baldwin, Diagnosis and Repair of the Pelvic Floor

MISSOURI

Mental Hygiene Conference—The Missouri Society for Mental Hygiene sponsored a mental health conference in St. Louis, March 26-28. Dr. Clarence M. Hincks, general director, National Committee for Mental Hygiene, New York, discussed "Mental Health—A Problem for the Community," and also addressed a meeting with the St. Louis Medical Society on "Twenty-Five Years of Mental Hygiene." Other speakers included Dr. Harold Douglas Singer, Chicago, on "The Meaning of Mental Health," John J. B. Morgan, Ph.D., professor of psychology, Northwestern University, Chicago, "Mental Health for Normal People," and Clifford Shaw, research sociologist of the Institute for Juvenile Research, Chicago, "Delinquent Careers."

Symposium on Diphtheria—The St. Louis Medical Society devoted a special meeting, April 29, to a symposium on diphtheria presented under the auspices of the St. Louis Health Department.

Joseph F. Bredeck, M.D., health commissioner, Diphtheria Immunization Status in St. Louis
Jacques J. Bronfenbrenner, Dr. P.H., Active Immunization Against Diphtheria
Jean V. Cooke, M.D., Toxoid versus Toxin Antitoxin
Joseph C. Willett, D.V.M., Virulence Tests in Diphtheria and Their Significance
Julius Rossen, M.D., Clinical Types of Diphtheria
John W. Eschenbrenner, Jr., M.D., Treatment of Laryngeal Diphtheria—Report of 650 Cases

The health department has been conducting a campaign against diphtheria.

NEBRASKA

State Medical Meeting at Omaha—The Nebraska State Medical Association will hold its annual meeting at the Fontenelle Hotel, Omaha, May 14-16, under the presidency of Dr. Joseph Bixby, Geneva. Guest speakers will be

Dr. Irving McQuarrie, Minneapolis, Some Recent Advances in the Field of Carbohydrates and Fat Metabolism in Children
Dr. Frederick A. Collier, Ann Arbor, Mich., Water Balance in Surgical Patients
Dr. Oliver J. Fay, Des Moines, Iowa, Medical Organizations and Political Control
Dr. Bernard L. Wyatt, Tucson, Ariz., Treatment of Chronic Arthritis
Dr. Willard Bartlett, St. Louis, An Inventory of Surgical Consideration Which Is Fundamental to Further Progress in Our Art
Dr. Emsley T. Johnson, Kansas City, Mo., Liver Damage Resulting from the Use of Synthetic Drugs
Dr. Russell L. Haden, Cleveland, Treatment of the Anemias
Dr. Joseph L. Baer, Chicago, Operative Obstetrics

Tuesday afternoon, May 14, there will be a special "cancer hour" at which speakers will be Drs. Herbert H. Davis, Earl C. Sage, Frederick C. Hill, and James F. Kelly, all of Omaha. An innovation this year will be informal luncheons and dinners at which guest speakers will conduct discussions. Tuesday evening, May 14, Drs. Collier and McQuarrie will discuss "Acute Appendicitis—When and When Not to Operate." Thursday noon, Drs. Johnson, Haden, and Baer will discuss "Possibilities

of Research in Medical Practice." Another special feature will be the showing of a motion picture on first aid and transportation of fractures by Dr. Hubley R. Owen, Philadelphia.

NEW YORK

State Medical Meeting at Albany—The one hundred and twenty-ninth annual meeting of the Medical Society of the State of New York will be held, May 13-15, in Albany at the Hotel Ten Eyck, and under the presidency of Dr. Arthur J. Bedell, Albany. The house of delegates will meet May 13; section meetings will be held in the mornings of the succeeding days and general sessions in the afternoons. Speakers at the general sessions will be

Dr. Walter L. Bierring, Des Moines, Iowa, President, American Medical Association, The Function of the American Medical Association
Dr. Olin West, Chicago, Secretary and General Manager, American Medical Association, Medicine of Today
Dr. Harrison S. Martland, Newark, N. J., Recent Advances in Pathology of the Cardiovascular System
Dr. Arthur F. Chace, New York, Treatment of Pneumonia
Dr. William P. Murphy, Boston, Facts Concerning the Treatment of Anemia
Dr. John J. Moorhead, New York, The Problem of the Broken Hip
Dr. Walter C. Alvarez, Rochester, Minn., Hints for Recognizing the Patient Who Will Probably Not Be Helped by an Abdominal Operation
Dr. George H. Hyslop, New York, Face Pain
Guest speakers who will address the sections are:
Dr. Frank H. Bethell, Ann Arbor, Mich., Application of Diagnostic Criteria to the Treatment of the Anemias
Dr. Stuart W. Harrington, Rochester, Minn., Surgical Treatment of Anterior and Posterior Mediastinal Tumors
Dr. Grover F. Powers, New Haven, Conn., Infant Feeding: Historical Background and Modern Practice
Dr. Louis W. Sauer, Evanston, Ill., Whooping Cough Vaccine as an Immunizing Agent
Dr. William Allen Pusey, Chicago, The Field of Dermatology
Dr. Frederick H. Verhoeff, Boston, Treatment of Sympathetic Ophthalmia with Antidiphtheritic Serum
Dr. Alan C. Woods, Baltimore, Allergy in Its Relation to Sympathetic Ophthalmia
Dr. George G. Smith, Boston, X-Ray and Radium Therapy in Diseases of the Genito-Urinary System
Dr. Alexander Randall, Philadelphia, Calculus in the Upper Urinary Tract.

The annual banquet will be held at the Ten Eyck Tuesday evening. Guests of honor will be the President and Secretary of the American Medical Association, Dr. Bierring and Dr. West, presidents of the medical societies of adjoining states and Gov. Herbert H. Lehman. Twenty-seven scientific exhibits will be displayed.

New York City

Eighth Harvey Lecture—John H. Northrop, Ph.D., of the staff of Rockefeller Institute for Medical Research, Princeton, N. J., will deliver the eighth lecture of the Harvey Society at the New York Academy of Medicine, May 16, on "The Isolation and Properties of Crystalline Pepsin and Trypsin."

Society News—Speakers at the monthly meeting of the Medical Society of the County of New York, April 22, were Drs. Menas S. Gregory, on "Psychiatry in General Practice, with Special Reference to Therapy," Eli Moschowitz, "Allergy to Life: An Interpretation of the Neurotic Constitution," Helen Flanders Dunbar, "Psychic Factors in Cardiovascular Disease," George Eaton Daniels, "Psychic Factors in Gastro-Intestinal Disease," and George W. Henry, "Psychic Factors in Thyroid Disease."—Drs. Martin E. Rehfuss, Philadelphia, and Albert F. R. Andresen addressed the Medical Society of the County of Kings, April 16, on "What Are We to Believe Regarding Modern Dietary Fads?" and "Dietary Principles in Treatment of Gastro-Intestinal Diseases," respectively.—Dr. Edward C. Vogt, Boston, addressed the New York Roentgen Society, April 15, on "The Noninfectious Diseases of the Hips in Children."—Dr. Russell S. Ferguson, among others, addressed the New York Pathological Society, April 25, on "Pathogenesis of Multiple Tumors of the Urinary Tract."—A symposium on syphilis and pregnancy was presented at a meeting of the section on obstetrics and gynecology of the New York Academy of Medicine, March 26, by Drs. John L. Rice, health commissioner, Joseph Earl Moore, Baltimore, James R. McCord, Atlanta, and Thurman B. Givan, Brooklyn.

OHIO

Dr. Blankenhorn Goes to University of Cincinnati—Dr. Marion A. Blankenhorn, professor of clinical medicine, Western Reserve University School of Medicine, has been appointed to the Gordon and Helen Hughes Taylor chair of internal medicine at the University of Cincinnati College of Medicine effective next September. He will succeed the late Dr. Roger S. Morris. Dr. Blankenhorn was graduated from Western Reserve in 1914, saw service during the World War and has served in various capacities on the faculty of his alma mater since 1920. He was appointed professor in 1929.

Dr Tom Douglas Spies, senior instructor in medicine at Western Reserve, was appointed at the same time assistant professor of medicine at Cincinnati

OKLAHOMA

State Medical Meeting at Oklahoma City—The forty-third annual session of the Oklahoma State Medical Association will be held in Oklahoma City, May 13-15, with headquarters at the Skirvin Hotel and under the presidency of Dr Le Roy Long, Oklahoma City. The house of delegates will meet Monday, May 13, general sessions will be held in the mornings and section meetings in the afternoons, May 14 and 15. At the general sessions speakers will be

Dr Charles M Pearce Oklahoma City state health officer, Public Health and Organized Medicine in Oklahoma
Dr Frank R Teachener Kansas City Mo Management of Brain Injury
Dr Roscoe G Leland Chicago, Director Bureau of Medical Economics American Medical Association Changes Confronting Modern Medicine
Dr Morris Edward Davis, Chicago Treatment of Toxemia Late in Pregnancy
Dr Max Thorak Chicago Modern Trends in Surgery

Dr Louis H Ritzhaupt, Guthrie president-elect, will give his official address at a general meeting Tuesday evening which will be followed by the president's reception and dance. The annual golf tournament will be played Monday at the Oklahoma City Golf and Country Club

PENNSYLVANIA

Harrisburg Graduate Assembly—The second annual graduate assembly sponsored by the Harrisburg Academy of Medicine will be held at the Penn Harris Hotel, May 23. The following program will be presented

Dr George B Eusterman Rochester Minn Gastric and Duodenal Ulcers
Dr George W Crile Cleveland Tumors of the Breast
Dr Elliott P Joslin Boston Prevention and Treatment of Diabetes
Dr James H Means Boston The Tongue and What It Teaches About the Patient's Condition
Dr William Wayne Babcock Philadelphia Appendicitis
Dr George E Pfahler Philadelphia Roentgenology and Its Relation to General Medicine

Bills Introduced—S 1127 proposes to create a board of chiropractic examiners and to regulate the practice of chiropractic. Applicants for licensure must be high school graduates and graduates of an incorporated chiropractic school or college approved by the board which requires a course of training therein of at least four years of eight months each with a minimum class attendance of 3000 forty-five minute hours. The bill proposes to define chiropractic as 'the science of locating and correcting any interference with nerve transmission and expression'. A license to practice chiropractic is not to confer on the licensee the right to practice surgery or obstetrics, to prescribe drugs or to administer anesthetics. H 2278 proposes to authorize the sexual sterilization of inmates of state institutions or of licensed institutions for the mentally defective, who are afflicted with hereditary forms of feeble mindedness, imbecility or idiocy, if the patient, if competent, or his legal guardian, consents

Philadelphia

Society News—Drs Scott Johnson and Henry T Chickering, New York, addressed the Philadelphia County Medical Society, April 10, on 'Diagnosis and Treatment of Influenza and "Treatment of Pneumonia" respectively—Dr John J Shea Memphis, Tenn addressed the Philadelphia Laryngological Society, April 2, on "Management of Allergic Conditions of the Ear, Nose and Throat—Dr Ralph R Rathbone Washington D C among others, addressed the Philadelphia Roentgen Ray Society, April 4 on Treatment of Epithelioma Involving Cartilage or Bone with Heavily Filtered Deep X-Ray Therapy—Among speakers at the annual health institute sponsored by the Woman's Auxiliary of the Philadelphia County Medical Society were Drs Chevalier L Jackson, on 'Danger of Swallowing Caustics or Foreign Bodies' and Stanley P Reimann 'The Menace of Cancer—Dr William H Park, New York, delivered the Frederick A Packard Memorial Lecture of the Philadelphia Pediatric Society, April 9 on "Value of BCG Vaccination in the Prevention of Tuberculosis in Children.—Dr Edward B Allen, White Plains N Y, among others, addressed the Philadelphia Psychiatric Society, April 12 on 'Psychotic Reactions in Hypoglycemia, or an Artificially Induced Hyperinsulinism, with Differential Diagnosis Between These and Psychoneuroses'—Drs Harlow Brooks, New York, and William D Stroud were speakers at the thirteenth annual meeting of the Philadelphia Heart Association April 24. Dr Brooks's subject was 'Play and Exercise in Heart Disease' and Dr Stroud reviewed the years work of the society

SOUTH DAKOTA

State Medical Meeting at Pierre—The fifty-fourth annual session of the South Dakota Medical Association will be held in Pierre, May 13-15, with headquarters at the St Charles Hotel and scientific sessions at the Masonic Temple. Mornings will be devoted to clinics conducted by Drs Charles B Wright, and Chester A Stewart, Minneapolis, Carl C Chatterton, St Paul, Russell M Wilder and Roger L J Kennedy Rochester, Minn. Among addresses to be given by guest speakers are

Dr Stewart Developmental Stages Through Which Tuberculosis Passes in Children
Dr Walter A Fanster, Minneapolis Use of Electrocoagulation in the Treatment of Rectal Carcinoma
Dr John D Camp Rochester Minn Significant Roentgenologic Changes in Cases of Low Back Pain
Dr Wilder The Diet in Diabetes High Carbohydrate or Low Carbohydrate
Henry F Vaughan Dr P H Detroit The Economic Aspect of Preventive Medicine—The Role of the Family Physician
Earl R Series Ph G Brookings S D Chronic Arsenic Poisoning as Developed from the Handling of Grasshopper Bait
Dr Chatterton Treatment of Some of the Deformities of Polymyelitis

The South Dakota Academy of Ophthalmology and Otolaryngology will meet, May 14 with the following guests Drs Harold I Lillie, Rochester, Minn, "Blood Stream Infection Associated with Suppurative Diseases of the Ear", John F Curtin, Minneapolis, "The Radical Mastoid Operation," and William H Stokes, Omaha, "Chronic Dacrocystitis and Its Surgical Management". The Woman's Auxiliary will celebrate the twenty-fifth anniversary of its founding at its annual meeting, May 14-15. Mrs R D Jennings, Hot Springs, first president, will be the honor guest.

WISCONSIN

Bills Introduced—S 345 proposes to omit from the law forbidding the torture of animals a proviso which excludes "experiments carried on for scientific research". *Correction* A 733 proposes to authorize the State Medical Society of Wisconsin, or any county medical society in a manner approved by the state society to "undertake and coordinate all sickness care of indigents and low income groups, through contracts with public officials, and with physicians and others, and by the use of contributions, cooperative funds and other means, provided only that free choice of physician within such contracts shall be retained and that responsibility of physician to patient and all other contract and tort relationships with patient shall remain as though the dealings were direct between physician and patient". The item concerning this bill appearing in the May 4 issue of THE JOURNAL inadvertently omitted the phrase italicized in the foregoing summary

GENERAL

Medical Bills in Congress—*Bills Introduced* S 2713, introduced by Senator O Mahoney, Wyoming proposes to authorize the erection of additional facilities at the existing Veterans' Administration facility, Cheyenne Wyo. H R 7524, introduced by Representative Fernandez Louisiana, proposes to extend the benefits of the United States Public Health Service to certain seamen. H R 7635 introduced by Delegate Dimond Alaska, proposes to extend the benefits of the United States Public Health Service to fishermen. H R 7835, introduced by Representative Luckey, Nebraska, proposes to authorize the erection of an addition to the existing Veterans' Administration facility at Lincoln, Neb. H R 7850, introduced by Representative Robison, Kentucky proposes to reenact all laws in effect March 19 1933 granting pensions to veterans of the Spanish-American War including the Boxer Rebellion and the Philippine Insurrection, their widows and dependents. Female contract nurses, but not contract surgeons, will be entitled to the benefits conferred by the bill

Bequests and Donations—The following bequests and donations have recently been announced

St Luke's Hospital New York \$10 000 outright a trust fund of \$300 000 and the residuary estate of \$1 176 463 Stuyvesant Square Hospital \$10 000 by the will of the late Mrs Mary Helena Tompkins
Jewish Memorial Hospital New York \$8 500 by the will of the late Philip Cohen
St Vincent's and Presbyterian hospitals New York \$2 500 each Mount Sinai Hospital a trust fund of \$10,000 and the residuary estate by the will of the late Bertha Weinman
Pennsylvania Lankenau and the Woman's Medical College hospitals Philadelphia and the Rivercrest Preventorium of the Kensington Dispensary for Treatment of Tuberculosis Montclair Pa., \$5,000 each by the will of the late Miss Cornelia Schiedt
Montefiore and Stuyvesant Square hospitals New York, \$7 500 and Hospital for Ruptured and Crippled \$5,000 by the will of the late Isa Nordlinger
St Vincent's Hospital \$2 000 United Hospital Fund \$1 500 and Greenwich Hospital \$500 all in New York by the will of the late Joseph Augustus Flynn
Salem Hospital, Salem, Mass \$5 000 by the will of the late Susan Northend

Awards for Research on Vitamin A—The Mead Johnson Vitamin A Research Award Committee announces that the award for laboratory research, \$5,000, has been divided between Karl E. Mason, Ph.D., Nashville, Tenn., and Dr. Simeon Burt Wolbach, Boston. Dr. Mason was honored for his work at Vanderbilt University on "Changes in the Vaginal Epithelium of the Rat After Vitamin A Deficiency." Dr. Wolbach, whose research was done in collaboration with Percy R. Howe, D.D.S., at Harvard University, dealt with "The Incisor Teeth of Albino Rats and Guinea-Pigs in Vitamin A Deficiency and Repair." The Mead Johnson Company, Evansville, Ind., established two awards for research on Vitamin A, Jan. 30, 1932. The committee decided to postpone bestowal of the main award of \$15,000 till 1936. Members of the committee are Drs. Isaac A. Abt, Chicago; Kenneth D. Blackfan, Boston; Alan G. Brown, Toronto, Ont.; Horton R. Casparis, Nashville; Henry F. Helmholz, Rochester, Minn.; Lawrence T. Rovster, University, Va.; Robert A. Strong, New Orleans; and Elmer V. McCollum, Sc.D., Baltimore, and Lafayette B. Mendel, Ph.D., New Haven, Conn.

Society News—The nineteenth annual meeting of the Association for the Study of Internal Secretions will be held in Atlantic City, June 10-11, at the Chalfonte-Haddon Hall. The American Academy of Pediatrics will have its annual meeting, June 7-8, at the Waldorf Astoria, New York. Chairmen for panel discussions will be Drs. Hugh Cabot, Rochester, Minn., on "Indications for Surgery in Pueria"; Lee W. Dean, St. Louis, "Prevention of Colds in Children"; Roy G. Hoskins, Boston, "Pituitary Glands," and Elmer V. McCollum, Sc.D., Baltimore, "Nutrition." The Medical Library Association will hold its thirty-seventh annual meeting in Rochester, N. Y., June 17-19, at the Rochester Academy of Medicine and the University of Rochester School of Medicine. Two delegates to the International Federation of Library Associations, meeting in Madrid May 19-30, will give reports at Rochester. This association has a membership of about 175 medical libraries of the United States and Canada. Mr. Charles Frankenberger, Brooklyn, is president. The American Proctologic Society will meet in Atlantic City, June 10-11, at the Marlborough-Blenheim.

Government Services

Colonel Reynolds Appointed Surgeon General of Army

Col. Charles R. Reynolds, now surgeon of the Second Corps Area, at Governors Island, N. Y., was appointed surgeon general of the army, April 29, with the rank of major general to succeed Major Gen. Robert U. Patterson, whose four-year term expires June 1. The new surgeon general is a native of New York and a graduate of the University of Pennsylvania School of Medicine. He is 57 years old. After serving briefly as a contract surgeon, he was commissioned in May 1901 as an assistant surgeon and rose through the grades to the rank of colonel in 1927. During the World War he received the Distinguished Service Medal, and in the Philippines in 1906 he received the Silver Star Citation for gallantry in action. In 1923 he was named commandant of the medical field service school at Carlisle Barracks, Pennsylvania. He was appointed to his post as surgeon of the Second Corps Area, Sept. 4, 1931. He also holds the rank of Officer of the Legion of Honor of France. Col. M. August Wroten Shockley, commandant of Letterman General Hospital at the Presidio of San Francisco, was named assistant surgeon general with the rank of brigadier general. Colonel Shockley was born in Fort Scott, Kansas, in 1874. He entered the army in 1898 and reached the rank of colonel in 1926. He also holds the Distinguished Service Medal and the cross of the Legion of Honor. General Reynolds' appointment is effective June 2, and Colonel Shockley's August 1.

CORRECTION

Clinical Spectroscopy—In the article by Gaul and Staud in THE JOURNAL, April 20, it was stated on page 1389 that Becker believes that the administration of 18 Gm or more of silver arspenamine is apt to be followed by argyria. The number should have been 15 instead of 18.

Foreign Letters

LONDON

(From Our Regular Correspondent)

April 13, 1935

Annual Report of Medical Research Council

The report of the Medical Research Council for 1933-1934 has just been published.

CLINICAL RESEARCH

The council has repeatedly stressed the importance of increasing the facilities for the scientific study of disease, particularly the need for a larger number of posts for whole time work, offering prospects such as already exist in the laboratory branch of medical science. It has for many years supported one clinical research unit with a whole time staff, the Department of Clinical Research at University College Hospital, under the direction of Sir Thomas Lewis. Two years ago it arranged for the establishment at the National Hospital for Nervous Diseases of a research department in neurology under the direction of Dr. E. A. Carmichael. When the post held by Sir Thomas Lewis received permanent endowment from the Rockefeller Foundation, funds were set free that enabled the council to establish a new clinical research unit at Guy's Hospital. One of the council's research workers, Dr. E. J. Wayne, has been appointed professor of pharmacology in the University of Sheffield, which is a whole time teaching and research position with full opportunity for clinical work. At King's College Hospital a new whole time appointment for clinical and research laboratory work has been established. At Middlesex Hospital a clinical research unit has been inaugurated. The new British Postgraduate School involves whole time professorships in medicine, surgery and obstetrics, which, though primarily teaching, are likely to give excellent opportunities for research work.

MENTAL DISEASES

The council has long regarded mental disorders as demanding active investigation. The number of mental defectives in England and Wales is about a quarter of a million and their proportion is believed to be greater than it was a generation ago. The council has therefore appointed a new committee for research into mental disorders consisting of representatives of psychiatry and medical psychology, neurology, physiology, biochemistry, pathology and genetics. The committee on sterilization referred to the council the question whether vasectomy before the attainment of maturity has any deleterious effect on development. The council was able to advise that evidence exists to show that no such effect results from vasectomy in young animals. A valuable line of research lies in the examination of the offspring of consanguineous marriages. An inquiry into cases of mental defect in similar and dissimilar twins is recommended as a means of testing the relative importance of genetic and environmental factors.

INHERITANCE AND DISEASE

In spite of the great advances in the biologic study of heredity, human genetics has been relatively neglected. Two years ago the council appointed a human genetics committee under the chairmanship of Prof. J. B. S. Haldane. A scheme for the extensive collection of data on the question of consanguinity has been framed. A large number of hospitals are cooperating by recording the parentage in respect to all their inpatients. The aim is to detect 'recessive' defects—characters usually not manifest in parent and child but transmitted in a latent form to appear when inherited on both sides. Up to the present, 'dominant' rather than 'recessive' inherited defects have been identified in man. Another important question is the part played by inheritance in the production of immunity to infec-

tion. The council has already published a report on this by Dr A Bradford Hill. It consists of a critical review of the published experimental data.

THE NATURAL HISTORY OF EPIDEMICS

The knowledge of the natural laws governing epidemics has been advanced by research on mice by Professor Topley and Greenwood. A practical study in man has been the investigation of infections in the more or less closed communities of boarding schools. The scheme is aimed chiefly at the diseases spread by droplet infection. A valuable research on active immunization against diphtheria among the pupils of the Greenwich Hospital School has been made by Dudley, May and O Flynn, medical officers of the navy. The conclusion is drawn that diphtheria is a manifestation of a firmly established symbiosis, that parasite and host act and react on each other in such a way that neither is destroyed. Total eradication of the parasite is not possible. The aim of preventive medicine is the establishment of conditions under which the bacterium can live harmlessly in human beings actively immune against it.

INFLUENZA

The study of influenza has been advanced by the discovery of Laidlaw, Andrewes and Smith that ferrets can be infected by material from the mucous membrane of patients suffering from the disease. A characteristic feverish catarrhal condition is produced in the animals and is transferable to other healthy ferrets. As the infective material was passed through a fine filter, before instillation into the ferret's nostril, the causative organism must be an ultramicroscopic virus. This virus shows affinities to that which American workers found to be the cause of "hog influenza." It has also been found that mice can be infected by intranasal inoculation, the illness being of a pneumonic type and generally fatal.

THE CHEMICAL CONTROL OF THE NERVOUS SYSTEM

The part played by specific chemical agents in the control of the nervous system is a new and interesting chapter in physiology. The researches of Dale make it highly probable that all messages from the central nervous system to voluntary muscles and other organs depend for their passage at particular points on the liberation of the unstable substance acetylcholine, while those sent through the sympathetic system have long been known to depend on a substance at least related to epinephrine. The specific reaction of the nervous system to drugs is well known, but the possibility is now raised that its activity depends on a series of "drugs" produced in the body. The recent work of Prof. R. A. Peters has shown that when vitamin B₁ is deficient in the body, parts of the brain become incapable of oxidizing carbohydrate completely, with the result that lactic acid accumulates, producing dire results. It has also been shown that in young animals vitamin A is essential for the integrity of the nervous system. Unlike the case of acetylcholine the effect is largely on the afferent side. In a number of nervous diseases—subacute combined degeneration of the cord, nervous ergotism, pellagra and lathyrism—the lesions are almost identical with those produced in young animals by vitamin A deficiency. It is thus probable that this experimental work will elucidate their causation. The work is also of interest as evidence that nerve cells aid the defense of certain tissues against infection. Thus xerophthalmia—long known to follow vitamin A deficiency—appears to be due to loss of neurotrophic control of the cornea, owing to degenerative changes in the gasserian ganglion and its fibers in the trigeminus.

Cancer and the Sex Hormones

Work by Dr J. W. Cook and Prof. E. C. Dodds has shown that compounds which are potent in the production of experimental tumors are closely allied in chemical constitution to the sex hormones. Synthetic compounds have been prepared that

induce tumor growth and excite estrus. This is the more suggestive as some resemblance exists between the cell multiplication due to estrogenic substance and the early stages of malignant growth and offers a clue of obvious importance, which may lead in some new direction.

Drug Waste Under the Insurance System Manchester's Addiction to Medicine

In a previous letter, the report of the Ministry of Health showing that in England the national health insurance system involved excessive prescribing and therefore waste of drugs was reviewed. The root of the evil is that the working class likes to take medicine whether for real or for imaginary ailments, and can obtain it without cost under the insurance system. The *Lancet* has suggested that a small charge should be made for drugs and this has been done in the Canadian insurance system. Attempts have been made to explain away this excessive prescribing but the argument that the cost of drugs per head under the insurance system in England is 50 per cent greater in England than in Scotland (where no such weakness for drugs exist) has proved unanswerable. In some parts of England the evil is much greater than in others. According to the *British Medical Journal*, Manchester "has maintained over a term of years a steady 50 per cent increase over the corresponding national averages. What the *Manchester Guardian* describes as "Manchester's notorious addiction to medicine" has led to a prolonged effort on the part of a special subcommittee appointed by the Manchester Insurance Committee to explain this unenviable preeminence. The subcommittee has attempted to arrive at some explanation by examination of statistics relating to industrial depression, climatic conditions, the incidence of sickness and many other matters, and in the end had to confess that all the voluminous statistics collected failed to reveal any explanation of Manchester's high drug cost. The failure to find a satisfactory explanation was only to be expected in view of the unsatisfactory one mentioned, which is referred to in an appendix to the report. The chief medical officer of the Ministry of Health suggested in his official report that during a long period of prosperity in the cotton mills the household custom was established in Lancashire of having a standing account with a physician and a firm belief in the bottle of medicine. The subcommittee finally quotes a warning to physicians that they may be fined for overprescribing.

Road Accidents

The number of road accidents involving death or injury in 1934 was 204,710, being 13,000 more than in 1933, and the number of persons killed or injured was 238,946, against 223,530 in 1933. The number of deaths was 7,343 against 7,202.

International Campaign Against Trachoma

The International Organization for the Campaign Against Trachoma met at the house of the Royal Society of Medicine. The president, Prof. Emile de Grosz of Budapest, said that during the fifteen years in which he had acted as commissioner for trachoma affairs he had set up the fundamental principle that the eye hospitals were the centers of antitrachoma prophylaxis. Trachoma was unable to spread in England because of the wise preventive measures and the work of the ophthalmic surgeons.

The president-elect Dr A. E. MacCallan, was the head of the antitrachoma campaign in Egypt for twenty years. He said that there were certain games or sports which tended to the dissemination of trachoma if a single player was infected. One was rugby football and the other was wrestling. It was not generally known that nearly all professional wrestlers had trachoma. Sporadic cases did occur in England. He had under observation two physicians, neither of whom had ever been out

of England or had ever seen a case of trachoma as far as he knew and yet who suffered from it. During the discussion it was stated that Glasgow was the only city in the British Isles where trachoma was notifiable

The Prevention of Tuberculosis by B C G Vaccination

The following guide as to the methods, in general, of using the Calmette-Guérin vaccine in children has been sent to physicians in France and its colonies

Vaccination			Revaccinations		
Age of Children	Preliminary Conditions	Method of Vaccination	Age of Children	Preliminary Conditions	Method of Vaccination
New born during first 10 days	Born viable birth before term is no contraindication	By mouth 3 ampules of B C G at intervals of 48 hours	1 3 7 and 15 years	1 Good general condition 2 Already vaccinated at birth	By mouth 8 ampules of B C G same as at birth at intervals of 48 hours
6 months to 2 years	1 Good general condition 2 Two negative skin reactions to tuberculin at 3 day intervals	Either (a) By mouth 3 ampules B C G as at birth at 48 hour intervals or (b) Subcutaneously 1 cc special emulsion of B C G 8c preferably in shoulder region	3 7 and 15 years	1 Good general condition 2 Already vaccinated between age of 6 months and 2 years revaccinations must be preceded by negative skin reactions	Preferably by mouth 3 ampules B C G same as at birth at 48 hour intervals
2 years and older	1 Clinical and radio scope examinations must be negative 2 Two preceding skin reactions to tuberculin at 7 day intervals must have been negative	By mouth 1 ampule B C G N R (nonreacting)	About every 5 years to adult age	1 Good general condition 2 Previously vaccinated once	By mouth 1 ampule B C G N R

Dosage of Diphtheria Antitoxin

A graduating thesis by Dr Zadour Valentin, based on the observation of 341 cases of diphtheria in the service of Dr Darre at the Children's Hospital has just been published. The antitoxin employed was prepared at the Pasteur Institute and preference given to simultaneous injection by both subcutaneous and intramuscular routes. Intravenous administration is employed only in cases of malignant diphtheria, in association with injection by the other two routes. The 46 mild cases went on to recovery after the injection of only 6,000 units of antitoxin. The author divides 133 more severe cases into two groups: those in which the thick whitish membranes were present only on the tonsils, and those in which the membranes were visible also on the palate and posterior pharyngeal wall. There were no evidences in either group of any malignancy in the form of edema of the mucous membranes or edema round the cervical lymph nodes, and there was a minimum of toxemia, with slight pallor and albuminuria. The mortality in these two groups was practically negligible, although one case had not been treated until the eighth day.

In the first group 12,000 units was given, and in the second group 24,000 units. These doses appeared ample in both instances, because when larger doses were given the membranes did not disappear any earlier nor was the incidence of paralyses any less. Paralysis was noted in 85 per cent of the cases of group A and in 185 per cent of those in group B. With the exception of one case, the paralyses were observed only in children first seen on the third day of the infection.

Malignant diphtheria occurred in sixty children. The clinical evidence included thicker, more grayish membranes with marked fetor and a tendency to bleed easily. There was also edema of the mucous membranes and of the neck and marked toxemia. The mortality in these sixty malignant cases was 36.6 per cent. There were eleven hypermalignant cases in this group of sixty in which the mortality attained as high a figure as 82.2 per cent. The latter cases showed a marked tendency to severe bleeding. If one excludes these hypermalignant cases, the mortality in the ordinary malignant type was only 26.5 per cent. Paralyses during convalescence occurred in 58.3 per cent of the malignant cases in which recovery occurred.

It is useless to give more than 60,000 units in the malignant form of diphtheria. The earlier the treatment is instituted, the less will be the mortality and likelihood of paralyses in all types of diphtheria. To be really efficacious, serotherapy must be employed before the third day in the usual forms and at the earliest possible moment in the malignant cases. A large initial dose of antitoxin is more important than smaller amounts given at intervals, hence a very large dose should be given as soon as the diagnosis has been made. In the form usually seen clinically, i. e., tonsillar or even beyond, from 12,000 to 24,000 units, in noncomplicated laryngeal cases 20,000 units, and as high as 60,000 units in the malignant forms, should be the

initial doses. One should not continue to give the antitoxin over too long a period, because the liver and kidneys are often involved in the toxic forms and there is, in addition, danger of serum reactions. Antitoxin has no influence on the paralyses. One ought to give the same doses to those who have been vaccinated against the disease as if vaccination by antitoxin had not been done. Examination of the blood shows that the amount of antitoxin attains its maximum on the third day and then gradually decreases in amount.

March 18, 1935

Census of Persons Who Attend the Sick

An official census was taken Jan. 1, 1934, of all persons in the German Reich who attend the sick in a professional capacity. A total of 278,353 persons were thus engaged, being distributed as shown in table 1.

TABLE 1—Distribution of Persons in the German Reich Who Attend the Sick in a Professional Capacity

Classification	Males	Females	Total Males and Females	Number per 10,000 Population in		
				Cities	Rural Districts	Combined
Physicians	44,474	2,501	47,275	11.4	4.3	7.3
Dentists	10,589	658	11,247	2.8	1.0	1.7
Licensed pharmacists	10,310	529	10,845	2.2	1.3	1.7
Assistant pharmacists and apprentices	3,378	1,801	5,289	1.2	0.5	0.8
Midwives	20,911	2,911	23,822	2.3	6.0	4.0
Dental technicians	17,726	2,272	19,998	4.1	2.3	3.1
Bath assistants attendants masseurs	9,246	5,164	14,410	2.8	1.0	1.7
Attendants on the sick	20,018	89,508	120,216	24.6	14.1	18.4
Nurses of infants and pre-school children		5,747	5,747	1.6	0.4	0.9
Nurses of puerperants		1,197	1,197	0.3	0.08	0.2
Disinfecting crews	4,784	188	4,972	0.6	0.9	0.8
Lay practitioners, etc.	10,888	3,378	14,266	3.6	1.3	2.2
Totals	129,019	149,334	278,353	57.5	32.3	42.7

As compared with the status of Dec. 31, 1931, the number of males has increased by 1.3 per cent, the number of females

by 5.2 per cent, and the total by 3.4 per cent. It is interesting to note that the number of masseurs, attendants, and the like, of dental technicians and of dentists has increased to a much greater extent, and particularly the number of nurses for infants and preschool children. On the other hand, the number of physicians showed a decrease of 1.4 per cent, also the number of pharmacists and midwives has diminished. The number of physicians reported as actively engaged, as of Jan 1, 1934, was 47,275. A comparison with the census taken Dec 31, 1931, reveals a decrease of 688 (1.4 per cent). The male physicians show a decrease of 734 (1.6 per cent), whereas the women physicians have increased by forty-six, so that the proportion of women physicians with respect to the total was 5.92 per cent, as against 5.74 per cent in 1931. Table 2 gives a survey of the changes in the number of physicians since 1876.

TABLE 2—Survey of Physicians Since 1876

Year	Total Number	Women Phys- cians	Number per 10 000 Population	Number per 100 Sq Kil	To One Physician	
					Inhabitants	Sq Kil
1876	13 728		3.3	2.5	3 112	89.3
1887	16 824		3.3	2.9	2 931	84.2
1898	24 725		4.0	4.0	2 192	21.9
1900	30 658		4.8	5.7	2 080	17.7
1927	43 583	1 739	6.9	9.3	1 461	10.6
1928*	45 948	2 202	7.2	9.8	1 289	10.2
1929*	47 534	2 421	7.4	10.1	1 349	9.9
1930*	47 268	2 611	7.3	10.1	1 365	9.9
1931*	47 063	2 755	7.4	10.2	1 351	9.8
1934†	47 275	2 801	7.2	10.1	1 380	9.9

* December 31
† January 1

It is evident, therefore, that during the past five years the figures have changed but slightly. Of the 47,275 physicians, 14,711, or 31.1 per cent, were specialists, with a classification as shown in table 3.

TABLE 3—Classification of Specialists in Germany

Specialty	Men	Women
Surgery	2,701	28
Gynecology and obstetrics	1 655	102
Dermatology and venereal diseases	1 750	63
Ophthalmology	1 291	69
Otology, laryngology and rhinology	1 464	12
Internal diseases	2 703	92
Diseases of children	841	287
Mental and nervous diseases	1,573	80
Totals..	13 978	733

Since 1931 there has been a further increase in the number of specialists, and thus likewise an increase in the percentage of specialists with respect to the whole body of physicians. Five per cent of the women physicians were specialists, which figure was a little lower than the percentage of women physicians with reference to the total. In the rural districts were found 3.4 per cent of the men physicians but only 2.0 per cent of the women physicians and 1.7 per cent of the specialists. The metropolitan districts are the best supplied with physicians, while in some of the rural districts the number is exceedingly small. In the ordinary medical rural districts of from 50 to 69 square kilometers there are only three or four physicians to 10,000 inhabitants whereas in Berlin there are 15.9 physicians per 10,000 of population in Hamburg 12.5, and in the average urban center 11.4.

Between 1931 and 1934 the number of lay practitioners increased by 1.7 per cent or by no means as rapidly as from 1930 to 1931 (8.4 per cent). Nevertheless Jan 1 1934, there were three lay practitioners to every ten physicians (in 1931 only 2.93). The increase was found almost exclusively among the men, 63.4 per cent of the male and 77.1 per cent of the female lay practitioners were engaged in urban centers.

MEXICO

(From Our Regular Correspondent)

March 2, 1935

Program of Child Care

The department of public health in Mexico City is working on a program for the care of children in the homes and dispensaries supported by the department. Dr Alfonso L. Alarcón, head of the branch, and the visiting physicians have met several times to discuss the program. To study the problems of children from social and scientific angles, during the preparation of the program, meetings of physicians, nurses and mothers have been held. The first meeting was successful because of the cooperation of the mothers. The department of public health supplies with milk many homes and public milk stations for infants and children. The public health laboratories in the Calzada de Tacuba have been improved with the aim of supervising the quality of milk supplied by the department.

Tourists and Public Health

Dr J. C. Geiger of the department of public health of San Francisco was in Mexico City, accompanied by his daughter, to study the requirements demanded by the authorities in Mexico of tourists. He is preparing a program related to the requirements of tourists between the United States and Mexico which will be submitted for the approval of the health authorities of both countries.

Prevention of Smallpox

In Chihuahua and some other states an outbreak of smallpox was recently observed, and the public health authorities have intensified the campaign of prevention. The work includes vaccination of school children and workers in factories and offices. Special brigades are working for this purpose in Aldama, Coyame and Rancheria Juarez.

Rural Hygiene by Correspondence

The present system of teaching hygiene by correspondence to rural teachers, which has been used during the last three years in Mexico, gives satisfactory results. The courses are given in the form of printed lectures prepared by special physicians. In this way, rural teachers receive a regular education in hygiene. They take examinations in their studies by correspondence, and if they meet the requirements they are given a diploma. February 28 was the closing day of registration for the 1935 course, in which about 4,000 rural teachers registered.

Marriages

HENRY R. DOUGLAS JR., Harrisburg, Pa., to Miss Frances Louise Ball of Indianapolis, in New York, February 22.

JOHN M. FLEMING, Spartanburg, S. C., to Miss Caroline Z. Miller of Williamsport, Pa., Dec 22, 1934.

HERBERT W. BARRON, Collegeville, Pa., to Miss Alice Williams of Conshohocken, February 23.

STANLEY OSBORN WILKINS, Tinton, Falls, N. J., to Miss Jane Macon Davis of Metuchen, April 17.

RAYMOND HOWE, Daytona Beach, Fla., to Miss Clyde Woodard of Miami, at DeLand, April 8.

HILL CARTER, Washington, D. C., to Miss Devereux Stokely of Birmingham, Ala., April 27.

AUSTIN C. LYNN, Philipsburg, Pa., to Miss Henrietta Brill of Philadelphia in March.

JOHN B. GRAY JR., to Miss Helen Cavanaugh, both of Columbus, Ohio, April 6.

CHARLES E. KENNEDY to Miss Mary Johnson, both of Smackover, Ark., March 29.

WILLIAM HARBIN JR., to Miss Elizabeth Warner, both of Rome, Ga., April 24.

Deaths

William Valentine Mullin ♂ Cleveland, Denver and Gross College of Medicine, 1908, secretary of the Section on Laryngology, Otolaryngology and Rhinology, American Medical Association, 1925-1928, and chairman, 1928-1929, member, in 1926 vice president, in 1933 treasurer and in 1934 secretary of the American Laryngological Association, member of the American Academy of Ophthalmology and Oto-Laryngology, the American Laryngological, Rhinological and Otolaryngological Society and the American Otolaryngological Society, fellow of the American College of Surgeons, served during the World War on the editorial board of the *Annals of Otolaryngology and Rhinology*, since 1926 head of the otolaryngology department of the Cleveland Clinic Foundation, aged 51, died, April 25, in the Cleveland Clinic Hospital, of cavernous sinus thrombosis.

Arthur Teall Mann ♂ Minneapolis, Harvard University Medical School, Boston, 1896, associate professor of surgery, University of Minnesota Medical School, assistant in surgery, 1900-1902, instructor, 1902-1907 and clinical professor 1907-1913, associate professor of surgery, University of Minnesota Graduate Faculty since 1915, incipient and past president of the Western Surgical Association, fellow and at one time governor of the American College of Surgeons, served during the World War, for many years consulting surgeon to the Minneapolis City Hospital, surgeon consultant to the U. S. Public Health Service, 1919-1923, aged 69, died, April 15, of carcinoma of the cecum.

George Clinton Straub, Brooklyn Long Island College Hospital, Brooklyn 1902, member of the Medical Society of the State of New York, served during the World War on the courtesy staffs of the Brooklyn Eye and Ear Hospital and the Prospect Heights Hospital, aged 58, died, April 8, in the Long Island College Hospital, of agranulocytic angina.

Edmund D. Putnam, Sioux Falls, S. D. Medical Department of Omaha University, 1897, past president of the Sioux Valley Medical Association, fellow of the American College of Surgeons, on the staffs of the McKennan Hospital and the Sioux Valley Hospital, aged 61, died, April 1, of cerebral arteriosclerosis.

Frank Samuel Boyer ♂ Allentown Pa., Medico-Chirurgical College of Philadelphia 1909, past president of the Lehigh County Medical Society, chief medical inspector in the public schools, on the staffs of the Sacred Heart and Allentown hospitals, aged 59, died, March 23, of cardiovascular renal disease.

Tyre Harrison Stice, Imola, Calif., Cooper Medical College, San Francisco, 1894, member of the California Medical Association, superintendent of the Napa State Hospital, aged 65, died, March 9, in the Victory Hospital, Napa, of chronic myocarditis, arteriosclerosis and cholelithiasis.

George Busby Campbell ♂ Nunda, N. Y. University of the City of New York Medical Department, 1892, served during the World War, for many years on the staff of the Utica (N. Y.) State Hospital, aged 66, died, April 7, in the Strong Memorial Hospital, Rochester, of pneumonia.

Alfred Heaton Schooley ♂ Terril, Iowa State University of Iowa College of Medicine, Iowa City, 1902, past president of the Dickinson County Medical Society, served during the World War, on the staff of the Birney Hospital, Estherville, aged 63, died, March 18, of carcinoma of the stomach.

Farquhard Campbell ♂ Kansas City, Kan., Western University Faculty of Medicine, London, Ont., Canada, 1903, at one time health officer, police surgeon and county deputy coroner on the staffs of the Bethany and Providence hospitals, aged 55, died, April 1, of cerebral hemorrhage.

Samuel Joshua Bernstein ♂ Brooklyn University and Bellevue Hospital Medical College, New York 1909, formerly on the staffs of the Jewish Hospital, the Trinity Hospital and the Beth Moses Hospital, aged 46, died, April 2, in Los Angeles, of coronary thrombosis.

Charles Edwin Butts ♂ Spokane, Wash. State University of Iowa College of Medicine, Iowa City, 1908, fellow of the American College of Surgeons, served during the World War, aged 51, on the staff of St. Luke's Hospital, where he died, March 30, of diabetes mellitus.

George Elden MacArthur ♂ Ipswich, Mass. University of Vermont College of Medicine, Burlington 1883, formerly chairman of the school committee, aged 76, on the staff of the Benjamin Stickney Cable Memorial Hospital where he died, April 11, of arteriosclerosis.

John H. Sutter, St. Louis, St. Louis College of Physicians and Surgeons, 1901, member of the Missouri State Medical Association, past president of St. Louis County Medical Society, aged 63, died, March 29, in the Evangelical Deaconess Hospital, of carcinoma.

Ross Fred Terrell ♂ Stigler, Okla., University of Tennessee Medical Department, Nashville, 1900, secretary of the Haskell County Medical Society, aged 59, died, March 14, in St. Edward's Mercy Hospital, Fort Smith, Ark., of spinal meningitis.

John E. Guy ♂ Milwaukee, Halinemann Medical College and Hospital, Chicago, 1904, member and past president of the Wisconsin State Board of Medical Examiners, on the staff of St. Mary's Hospital, aged 55, died, April 10, of coronary embolism.

Sidney Manson Edmondson ♂ Clayton, N. M., North Carolina Medical College Davidson, 1906, past president of the Union County Medical Society on the staff of St. Joseph Hospital, aged 53, died in March in Texline, Texas, of angina pectoris.

Albert Lee Peters, Hurricane, W. Va., Louisville (Ky.) Medical College, 1894, member of the West Virginia State Medical Association, served during the World War, aged 68, died, February 21, of myocarditis and cardiac asthma.

James Henry Trainor, Newark, N. J. Columbia University College of Physicians and Surgeons, New York 1903, member of the Medical Society of New Jersey, aged 53, died suddenly, March 15, of chronic myocarditis.

Edward Adolph Pinkus, Brooklyn, Syracuse University College of Medicine 1923, served during the World War, aged 41, on the staff of the Jewish Hospital, where he died, April 5, of heart disease.

George Duncan Macleod, Cleveland, Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1898, aged 69, died, April 3, of arteriosclerotic heart disease.

Ernest Milton Parrett, Columbus, Ohio, Starling Medical College, Columbus, 1899, on the staff of the Grant Hospital, aged 59, died, April 15, of bronchiectasis and chronic myocarditis.

John Henry Sevier, Brownsville, Tenn., Vanderbilt University School of Medicine, Nashville, 1883, aged 72, died, April 15, in the Baptist Hospital, Memphis, of cerebral hemorrhage.

Arthur William Brennan, Minneapolis, St. Louis University School of Medicine, 1911, served during the World War, aged 47, died, March 27, of pulmonary tuberculosis.

James Henry Thompson ♂ Ashtabula, Ohio University of Toronto Faculty of Medicine, 1927, on the staff of the Ashtabula General Hospital, aged 33, died, April 5, of pneumonia.

John W. Phemister, Houston, Mo., St. Louis College of Physicians and Surgeons, 1890, aged 69, died, February 21, in a hospital at Rolla, of carcinoma of the sigmoid.

Joseph Callahan Bussey, Louisa, Ky. Medical College of Ohio, Cincinnati, 1889, aged 76, died, March 27, of arteriosclerosis, chronic nephritis and uremia.

Robert Joseph St. Jacques, Marlboro, Mass., School of Medicine and Surgery of Montreal, Que., Canada, 1879, aged 78, died, March 1, of angina pectoris.

Alonzo D. Thornton, Goreville, Ill. Chicago College of Medicine and Surgery, 1913, aged 52, died, February 1, in the Herrin (Ill.) Hospital, of pneumonia.

Oliver Gatch Chance ♂ Cincinnati University of Cincinnati College of Medicine, 1924, aged 34, died, April 8, in the Christ Hospital, of spinal meningitis.

Joseph Alfred Robertson, Hot Springs National Park, Ark. Memphis (Tenn.) Hospital Medical College 1897, aged 71, died recently of cholelithiasis.

John W. Cain, Waukon, Iowa, Rush Medical College, Chicago, 1883, aged 79, died, March 25, of arteriosclerosis, chronic nephritis and uremia.

W. H. Plummer, Winfield, Ark. (licensed in Arkansas in 1903), also a lawyer, preacher and postmaster, aged 66, died, April 11, of heart disease.

Leander K. Shipman, New London, Conn. New York Homeopathic Medical College 1883, aged 81, died April 11, of cerebral thrombosis.

William Eugene Settle, Wynne, Okla. Louisville (Ky.) Medical College, 1894, aged 68, died, March 12, of myocarditis.

Harry Wilbur Sims, Columbus, Ohio. Rush Medical College, Chicago, 1908, aged 53, died, March 29, of heart disease.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request

PREMATURE ALOPECIA IN WOMAN

To the Editor—A woman aged 53 has had an itching scalp and falling of the hair for the past two years. The general health, aside from nervousness of the menopause is good. The scalp is clean except for a few minute scales of a seborrheic nature. The scalp and hair are quite oily the condition returning in three or four days after a shampoo as does the intense itching. There are no irritated or sore spots on the scalp. There is no evidence of syphilis. The patient has never had permanent waves or other severe hair dressings nor has she permitted hair dressers to use severe or strong preparations on the scalp. As in treatment, sulphur, resorcinol and the usual category of medicaments have been used also small doses of quartz light. The hair does not come out in spots but it is thinning all over the head. I will appreciate any suggestion. Please omit name.

M D, Oklahoma

ANSWER.—The description is that of premature alopecia in a seborrheic individual. The following pomade may be vigorously massaged into the scalp twice daily or applied at night and washed out in the morning oil of cade 12 Gm precipitated sulphur, 6 Gm, salicylic acid 3 Gm, sufficient official ointment of rose water to make 60 Gm. The oil of cade may be omitted, but the preparation is then less efficient. The scalp should be shampooed with tincture of green soap at least three times weekly. It should be lathered and rinsed several times until abundant foamy lather is obtained, which should be left on for from fifteen to thirty minutes. The hair should then be dried well. Frequent massage and shampoos will mechanically remove some of the loose hairs so that the hair loss is temporarily aggravated. The hair may be bobbed for convenience. Daily exposure to the air cooled mercury vapor lamp is efficacious in sufficient dosage to produce tanning of the scalp. After a few weeks the pomade may be replaced by the following scalp lotion corrosive mercuric chloride, 0.125 Gm, chloral hydrate, 0.5 cc tincture of capsicum 1 cc alcohol 60 cc, perfumed spirit 60 cc, sufficient water to make 240 cc. A small amount should be poured into the scalp daily, followed by massage. If there is any evidence that the itching is due to the menopausal nervousness a daily nap and phenobarbital will lower the patient's irritability.

PTOSIS OF UPPER EYELIDS

To the Editor—In THE JOURNAL Dec 22 1934 appears a query and minor note entitled Ptosis of Upper Eyelids. As Dr Guyton's and my own symptoms began with an intermittent ptosis which a number of eminent physicians failed to recognize as a symptom of myasthenia gravis we are wondering how the person who answered this inquiry ruled out myasthenia gravis.

HARRIET EDGEWORTH Warm Springs Ga

ANSWER.—The ptosis described was not intermittent, did not come on when the patient was tired, and the doctor specifically states that the general musculature was normal. While ptosis is a common finding in myasthenia gravis, it is intermittent present when the patient becomes fatigued, and occurs most often in women around the age of 50. In these cases the duction tests show the extrinsic ocular muscles stronger than normal.

The condition described is most likely a paresis resulting from an influenza.

Aminoacetic acid and epinephrine or ephedrine can be used as a therapeutic test. These would help myasthenia gravis as well as any muscular weakness.

TREATMENT OF SYPHILIS

To the Editor—I have two patients a mother aged 29 and a son aged 6 who both have 4+ Wassermann reactions. The father's reaction is negative. The mother had some treatment apparently with neosarsphenamine about ten years ago. Neither mother nor son has any external signs of syphilis. The mother has had two spontaneous abortions in the past two years. The son has very marked internal strabismus. Will you please outline the best treatment for each? Please omit name.

M D Pennsylvania

ANSWER.—Authorities differ as to what constitutes the 'best' treatment for syphilis. Modern syphilotherapy favors a combined attack with heavy metals preferably a bismuth compound either conjointly or alternating with courses of one of the arsenamines. According to one recent authority from twenty to thirty injections of arsphenamine intravenously and perhaps

double that number of injections of a bismuth compound intramuscularly will confer a high rate of protection against recurrence and late accidents in early cases. In addition to this treatment the mother should receive iodides between courses and mercurial inunctions may be substituted for one of the bismuth courses. The child who obviously has congenital syphilis, should receive substantially the same treatment in correspondingly smaller doses. The correspondent would do well to consult "Modern Syphilology," by Stokes, or the "Treatment of Syphilis," by Schamberg and Wright, or "The Modern Treatment of Syphilis," by Moore for details as to dosage, frequency of injection, and instructions how to guard against possible dangerous reactions to the drugs employed. Unless the practitioner is well versed in the treatment of syphilis he would do well to send his patients elsewhere.

NUMBNESS OF FINGER IN FURRIER

To the Editor—A man aged 40 whose general physical condition is excellent and who is 6 feet (183 cm) tall and weighs 195 pounds (88 kg) complains of numbness and coldness in the lower half of the right index finger. There is also slight tingling in the tip of the finger and a marked impairment in the sense of touch. He is a furrier and relies on his sense of touch in this particular finger to determine the quality of furs. In childhood both hands were frozen on two or three occasions. In 1915 he sustained a gunshot wound of his right hand and arm and fourteen of these shots are in the hand and arm and one of them lies along the medial side of the right index finger. There is no evidence of lead poisoning. On examination the finger is slightly bluish over the distal phalanx is not swollen puts on pressure as none of his other fingers do is cold and there is a complete loss of light touch but perceptions of heat and cold are differentiated. Kindly advise as to what the possible etiologic factors may be and what course of treatment I should pursue.

H O TUCKER M D Santa Barbara Calif

ANSWER.—Numbness and coldness of the fingers of a man who does not have any known existing disease suggests the following possibilities. 1. He may have early disease of the digital arteries, which may be thrombo-angitis obliterans or the digital vessels or arteriosclerosis obliterans or some unidentified form of arterial disease. Persistent coldness of the finger and the presence of color changes on exposure to cold may help in the diagnosis. The presence or absence of pulsations in the palpable arteries should be sought for. Arteriography has been of great help in the identification of occlusive lesions of the peripheral arteries. 2. He may have some disturbance of the peripheral nerves with a secondary vasospastic disturbance. The presence of shot in the arm and finger suggests the effects of a foreign body on the nerve. It seems more likely from the unidigital distribution of the complaint that the foreign body in the finger may be responsible. The coldness of the finger could be related to irritation of sympathetic nerves in the peripheral mixed nerve. The loss of light touch is frequently found in any disease in which the circulation is diminished. Warming the fingers, by putting the hands in warm water frequently demonstrates restoration of the sense of touch by improving the circulation. Cervical ribs should be ruled out as this condition may produce paresthetic symptoms in the fingers. Early scleroderma is ruled out by absence of changes in the skin.

The treatment depends on the diagnosis. As long as the circulation is fairly adequate, as demonstrated by preservation of normal color of the skin when the hands are elevated, no serious sequelae should follow. Removal of the lead pellets should be considered.

HERPES OR ALLERGY

To the Editor—A married woman aged 30 with no complaints other than an intractable constipation has for fifteen years suffered from multiple ulcers of the peptic type on the lips cheeks and tongue. Relief of the constipation does not have any effect on the occurrence of the ulcers. A chronic infection of the nose and throat has been cured, with no improvement in the condition of the mouth. Diet and conditions of hygiene cannot be criticized. Her dentist assures me that the teeth are not rough or irregular. The bowel is neither of the spastic nor the atonic type. The oral administration of phenyl salicylate 20 grains (1.3 Gm) a day in divided doses gave no benefit. What more can you suggest? Please omit name and address.

M D New York

ANSWER.—The lesions on the lips, cheeks and tongue may be either a chronic herpes or more probably oral manifestations of a gastro intestinal allergy. The latter may be determined by keeping a food diary for two or three weeks and possibly finding a relationship with any foods and the occurrence of the lesions, that failing, a series of skin tests with food allergens might be carried out. Finally elimination diets might be tried such as suggested by Rowe. The constipation should be treated by high residue diets drinking several glasses of water daily, exercise, and the occasional use of a retention oil enema.

TUMOR OF HYPOPHYSIS

To the Editor—M C a boy, aged 12½ years was seen three and one-half years ago with a complaint of increased thirst, poor appetite, restless sleeping and the passing of great quantities of water. The birth and the developmental history were normal. At the age of 4 years he had a left frontal sinus operation following acute ethmoiditis from which he apparently made complete recovery. Medical and neurologic examinations at this time were negative. Complete Wassermann tests and determination of the serum potassium and calcium roentgen examination of the skull and eyeground examinations were all negative. Complete chemistry stool and complete urine examinations were negative. The twenty-four hour intake varied from 6 to 8 quarts with a corresponding output. Following the diagnosis of diabetes insipidus solution of pituitary by hypodermic injection in adequate dosage was given to which he responded a short time by decreased intake and output but after ten days the solution of pituitary seemed to have lost its effect even though the dose was increased. Restriction of the fluid intake resulted in extreme restlessness, headaches, dryness of the hands and feet and cracking of the lips and general body discomfort although the output was lowered. Ampules of pitressin by hypodermic injection produced the same effect as the solution of pituitary giving relief for a short time followed by a return of the high intake and output. Amidopyrine by mouth reduced the intake and output greatly but produced extreme nausea no matter in what form given so that the medical treatment was discontinued. These symptoms in the status of the case continued unchanged until one year ago when in addition to the symptoms of polyuria and increased thirst he began to have spells of nausea vomiting and dizziness which lasted for three days and seemed to occur periodically every two weeks. During this time he lost weight was unable to retain any nourishment and was entirely incapacitated. These symptoms were somewhat ameliorated when 40 mg. of pituitary powder was given intranasally three times a day but the spells of nausea dizziness and vomiting have persisted up until the present time. He has been thoroughly checked at the Johns Hopkins Hospital Neurological Institute. Encephalograms and repeated neurologic examinations have been persistently negative. Complete chemical tests taken before during and after the spells of nausea and vomiting proved negative. I would appreciate any information as to the diagnosis and management of this case.

A S FINKELSTEIN M.D. Newark N. J.

ANSWER—The history of this patient suggests a lesion of the hypophysis or probably more correctly the hypothalamus. The careful studies that have already been made would tend to exclude the diagnosis of tumor in the region of the diencephalon. Other lesions of the hypothalamus may cause vomiting, headache, nausea and loss of weight. Nuclear degeneration from disease, postencephalitic lesions, gummas, cysts, lymphomas, multiple sclerosis and hemorrhage may produce symptoms that are similar to those caused by tumors and may be not unlike those which are present in the case described. The supra-optic nucleus has been considered the center of water metabolism, and lesions of this region may cause polyuria and other symptoms complained of by the patient. Many writers suggest that occasional lumbar puncture may give relief in some cases. Solution of pituitary and ampules of pitressin, which have already been tried in this case, are recommended.

LOSS OF POTENCY IN IMMUNE SERUM

To the Editor—In a recent issue of a veterinarian journal I noted a statement to the effect that a blood serum gradually decreased in its agglutinative power on aging. This statement was made with particular reference to *Brucella abortus* or Bang's abortion disease in cattle and man. Has there been any publication that would uphold such a statement? Several times I have made checks on positive serum reacting to this disease and the agglutinative power always appears to remain strong even up to two weeks time. Your information will be greatly appreciated.

ROGER D. MINSTER, Bacteriologist, Nampa, Idaho

ANSWER—It is true in general that immune serum gradually loses in antibody strength on standing but this loss is gradual and it may take months and even years before the loss becomes complete. An agglutinating serum against *Brucella* would be expected to retain its agglutinins much longer than two weeks if properly preserved in the icebox.

WARTS AROUND FINGERNAILS

To the Editor—Kindly advise best treatment of papillomatous growths around and underneath the fingernails. Electrodesiccation and x-rays have been used but the growths recurred. Please describe local anesthetic method for electrodesiccation at this area. Please omit name.

M.D. New York

ANSWER—Warts often can be cured by suggestion and many of the cures from mild chemical or physical measures may really be faith cures. Even after the failure of electrodesiccation and x-rays this may be worth trying, but the chances of success are much smaller than they are in untreated cases.

Electrodesiccation or the electrocautery will cure them if carried far enough. After a treatment that seems adequate,

the patient should return regularly for inspection and the cauterization should be repeated on any areas incompletely treated.

Anesthesia sufficient for small areas can be obtained by injecting a 2 to 4 per cent solution of procaine hydrochloride directly about and under the wart to be treated. For patients with many warts on one finger, a circle of deep injections proximal to the area to be treated will anesthetize the whole tip of the finger. Epinephrine should not be used for fear of serious damage to the circulation.

DYSPNEA AND SWALLOWING

To the Editor—I have a case under observation of a woman aged 64, formerly a trained nurse, who is active energetic and in good health. During the last three years she has at rare intervals viz. once or twice a year, been seized with an attack of dyspnea. The attack is brought on by some failure to swallow properly which results in a fit of coughing. Suddenly during the latter she is seized with a sensation of being strangled gasps for breath totters and becomes frightened. The seizure is painful to witness. The struggle for air and the terror soon pass leaving the patient in a perfectly normal condition. I take it that this is a reflex spasm of the bronchi because I have heard of bronchospasm and have not heard of laryngeal spasms in normal people. I have read of death resulting from bronchospasm in persons of frail constitution but this woman is strong though of advanced years. Will you be so kind as to inform me how the patient can meet these crises herself also what I might do to assist her? These questions I should like to have answered promptly. Less urgent is my request for references to the literature on this subject. Please omit name and city.

M.D. Pennsylvania

ANSWER—These attacks are apparently initiated during the act of swallowing. The first manifestation is coughing, indicating irritation of the larynx, followed by "strangling," and eventually severe laryngeal spasm preventing inspiration or expiration and giving the sensation of acute suffocation.

The disturbance of swallowing is apparently in the pharynx or hypopharynx and would suggest impairment of innervation of the act of deglutition due to paresis of the muscles. As it occurs at long intervals it may be associated with a too rapid attempt of the act and some of the food flows into the larynx.

The patient should be cautioned to masticate her food thoroughly and to swallow slowly. The prognosis is good unless there are signs indicating progressive bulbar palsy.

PSORIASIS

To the Editor—I have a girl aged 3½ years under my care who has had psoriasis lesions on her trunk and scalp for three months. What is the most satisfactory method of treating this condition and what will be the prognosis after she reaches adult life? Please omit name.

M.D. California

ANSWER—The application of an ointment containing 3 per cent of salicylic acid and from 3 to 5 per cent of ammoniated mercury to the affected spots each night, and removing it with any loose scales, with olive oil the next morning, is of value in these cases. Starch and alkaline baths are also advised. If the case is one of true psoriasis, the possibility of recurrent attacks, with remissions of variable duration, for the rest of her life is highly probable. Restriction of protein and fat has also been recommended in psoriasis. The use of vitamins A and D by mouth, or salicin, or the careful administration of arsenic is of value in cases that resist local and dietary treatment.

TREATMENT OF SYPHILIS IN PATIENT WITH SMALL VEINS

To the Editor—I would appreciate your advising me of any suggested method you may know about for treating syphilis by the injection method in a patient who has unusually poor veins. Please omit name and address.

M.D. New York

ANSWER—It is rare when patients have veins that are not suitable for intravenous injection. This does, however, occasionally occur, particularly in very obese individuals.

When the veins cannot be easily reached, the patients may be treated if arsphenamine is indicated, by intramuscular injections of sulpharsphenamine or by placing entire reliance on heavy metal therapy, which can be injected into the buttock, in the form of either bismuth or mercury compounds. The type of heavy metal and the choice of the particular drug are open to considerable variation. Generally speaking, the insoluble salts of both mercury and bismuth, such as mercuric salicylate and bismuth subsalicylate, given once weekly, are most widely used by syphilologists. If sulpharsphenamine is given it may be used weekly in doses of 0.15 Gm. to each 25 or 30 pounds of body weight and under these conditions heavy metal should of course be used.

MULTIPLE SCLEROSIS

To the Editor—Is it advisable to search for focal infections in multiple sclerosis and eliminate them if found? If a positive complement fixation test for gonorrhea is found in a patient with multiple sclerosis after the patient has supposedly been cured of gonorrhea five years and is at present without symptoms referable to the old gonorrheal infection, is a stock gonococcus vaccine treatment advisable? If so what line of vaccine treatment should be pursued? What is the consensus as to fever therapy or quinine hydrochloride in multiple sclerosis? Has there been any confirmatory literature on lead as a possible cause of multiple sclerosis since the article in the *Journal of Neurology and Psychiatry* in February 1934? How long may a remission in multiple sclerosis last? Is the prognosis different in the sexes? Is there anything to be done for spasticity? How much exercise is advisable in a patient with slight spastic paresis of one leg? Please omit name
M D, Massachusetts

ANSWER—Multiple sclerosis is considered by some investigators to be degenerative and by others to be inflammatory in nature. It is advisable to clear up any focal infection when present. There is no causal relationship between gonorrhea and multiple sclerosis. Gonococcus vaccine treatment in multiple sclerosis is not advised. Typhoid and paratyphoid vaccine is used often in retrobulbar neuritis of multiple sclerosis in the hope that the process in the involved eye may be arrested. Quinine hydrochloride should be used in every case of multiple sclerosis unless the patient is sensitive to it. There has been no confirmatory literature on lead as a possible cause of multiple sclerosis since 1934. A remission in multiple sclerosis may last from weeks to years. There have been isolated instances of complete recovery. There is no difference in prognosis for the two sexes. Absolute rest in bed is probably the best treatment for spasticity in multiple sclerosis.

PERLÈCHE

To the Editor—What would you advise for a woman aged 55 who for twelve years has complained of fissures from the corner of her mouth and her nose that persistently crack open and become sore? Various ointments such as Calmetol have been tried. She has received dilute hydrochloric acid for gastric achylia with no permanent benefit also silver nitrate locally. Although the basal metabolic rate was only -3 per cent she was given desiccated thyroid 2 grains (0.13 Gm) daily with but a slight improvement.
M D Wisconsin

ANSWER—The condition conforms to that seen in perlèche. This is a condition most frequently seen in children but which may occur in adults and in which the skin at the corners of the mouth becomes macerated and small transverse fissures appear showing a reddened base near the lip when it is stretched. This condition is an infection due to cocci, moniliae or cryptococci. The involvement of the nose could occur by secondary extension. Syphilis, of course, must be ruled out by serologic tests. If the condition is perlèche, the areas should be painted with a 2 per cent solution of gentian violet. The use of 2 per cent ammoniated mercury ointment is also of value in some of these cases.

SILVER DEPOSITS IN SKIN

To the Editor—I have a patient who is employed in an industry which necessitates immersing his hands in silver solutions whereby there remains on his skin a deposit of silver sulphide that is extremely difficult to remove. He has experienced no effects either locally or systemically from his exposure. I am interested in finding out whether or not there is anything that he can use to remove this deposit from his skin. Please omit name.
M D Massachusetts

ANSWER—The removal of silver deposits from the skin is a difficult procedure. Sodium thiosulphate intravenously or an intradermal injection of 6 per cent sodium thiosulphate and 1 per cent potassium ferricyanide, as recommended by Stillians and Lawless (*THE JOURNAL*, Jan 5 1929), may be tried.

KERATOSIS OF PALMS AND SOLES

To the Editor—A girl baby, aged 3 months, has had thick rough dry palmar and plantar epidermis since the age of 6 weeks. The physical examination and laboratory studies give negative results. The blood Wassermann reaction is negative in the child and her mother. The family history is negative except that the mother has had the same condition since about the age of the child. A diagnosis of hereditary or congenital keratosis has been made. I would like your opinion as to diagnosis, prognosis and treatment. Please omit name.
M D Iowa

ANSWER—This case is one of congenital symmetrical keratosis of the palms and soles. In the inherited cases the prognosis must be guarded as the complete removal of the disorder is not often accomplished. The skin, however, may be kept soft by applying an ointment consisting of from 2 to 5 per cent of salicylic acid in petrolatum. Bathing of the parts to secure

maceration, shampooing with soft soap, and the subsequent application of a bland ointment are also of value. When the child gets older, x-rays may be cautiously used in fractional doses.

STERILITY IN CRYPTORCHIDISM

To the Editor—A man aged 24 with bilateral cryptorchidism is in good health, both testes are apparently intra abdominal. Puberty occurred at about 15 years and male sex characteristics and sexual appetite are normal. He never considered marriage because of his condition and he has considered himself sterile. He believes himself the only one to have had intercourse with a now pregnant woman about the time she became pregnant. The lady confirms him in this belief. Examination of a condom specimen twelve hours old showed no spermatozoa or heads of spermatozoa. Would a fresher specimen possibly show spermatozoa? Please advise as to the possibility of a man not being sterile. Please omit name.
M D, Pennsylvania

ANSWER—Cryptorchids are as a rule sterile. The condom specimen examined shows almost conclusively that the patient is sterile, for, even if examined at this late date, spermatozoa though dead ought to be found in a normal specimen. There is no harm, of course, in confirming this information by obtaining a fresher specimen. The chances are, however, that he is absolutely sterile. A trial of injections of gonadotropic substance from the urine of pregnancy (antuitrin S or follutein) should be made in the hope of causing a descent of the testicles, and, if not successful, an operation should be advised.

TOURNAY SIGN

To the Editor—Will you kindly let me know the meaning of the following sign? "Tournay's sign is always present in Horner's syndrome. Horner's syndrome was recently discussed at a meeting of ophthalmologists and Tournay's sign was mentioned from the literature. No one present ever heard of the term."
M D, New York

ANSWER—The Tournay sign consists in a unilateral dilatation of the pupil of the abducting eye on extreme lateral fixation. The dilatation begins after an interval of three to five seconds and it is about 0.5 mm in extent. It persists as long as the lateral fixation is maintained, although hippus-like variations occur. According to Franceschetti, this phenomenon was described by Gnanelli before Tournay's publication in 1927.

VISUAL ACUITY IN CHILD

To the Editor—How early in life does a child see?—a question that was suddenly popped at me. Please omit name.
M D, Ohio

ANSWER—A baby sees as soon as it emerges from the birth canal. The visual acuity is low, however, for the macular area of the retina is not yet differentiated. Visual acuity as judged by adult standards depends on a complete differentiation of the macular retina, and this differentiation does not begin until about the sixth week of extra-uterine life. It is completed between the third and fifth months. It is believed that at birth the macular retina has about the same visual efficiency as does the adult retina that lies 15 or more degrees away from the macula, namely, about one forty-fifth of standard visual acuity.

NEW YORK CLIMATE AND BRONCHITIS

To the Editor—Can you inform me or are there any data available as to the advantages or disadvantages of southeastern New York State over the western part of New York State (Buffalo) in the protection of a child from recurring bronchitis? I will appreciate any aid you may be able to give me concerning this problem.
H F POHLMANN, M D Middletown, N Y

ANSWER—The climatic conditions in the western part of New York State, and the southeastern part, are in a general way comparable. From the climatic standpoint there should be no advantages or disadvantages in relation to a child suffering from recurring bronchitis.

COMPARATIVE REACTIONS FROM SCARLET FEVER AND DIPHTEHRIA ANTITOXINS

To the Editor—In the Year Book of General Medicine 1935 page 98, Hunt says that the reaction from scarlet fever antitoxin is not more severe than the reaction of diphtheria antitoxin. I am wondering whether this statement is not questioned by most writers.
J D MICHIE, M D Childress Texas

ANSWER—On the contrary, writers who have had extensive experience agree with Dr Hunt.

Book Notices

Sculptures in the Living Rebuilding the Face and Form by Plastic Surgery By Jacques W Mollinik M D With a foreword by Wendell C Phillips M D Cloth Price \$3 Pp 203 with 70 illustrations New York Lancet Press 1934

This interesting little book is concerned chiefly with the social and esthetic aspects of deformities principally those of the face It is an attempt to acquaint the physician and through him the layman with the possibilities of the legitimate practice of plastic surgery Much of the space is given over to a discussion of the psychic and legal aspects of facial deformities, real or fancied The history of this interesting art is briefly sketched and there is a fair description of the anatomy and physiology of the structures involved Numerous blemishes and other deviations from normal are mentioned and the treatment is indicated So far as technique is concerned the book is superficial One could hardly expect a work of this size to devote much space to the actual details of the operative procedures Surgeons desiring information on this phase of the subject will have to seek elsewhere Mollinik's book is more general in its scope It delineates the boundaries of ethical plastic surgery in contradistinction to the oft publicized quackery masquerading as such with its attendant evils, misconceptions and complications The physician who reads this book will gain a clearer conception of what plastic surgery can accomplish at the hands of the experienced and be thereby enabled to advise his patients intelligently

The Practice of Refraction By Sir Stewart Duke Elder M A D Sc Ph D Ophthalmic Surgeon and Lecturer in Ophthalmology St George's Hospital London Second edition Cloth Price \$4 Pp 383 with 180 illustrations Philadelphia P Blakiston's Son & Company Inc 1935

This edition was written about seven years after the first. As some of the redundant matter has been eliminated, it is smaller than its predecessor In the preface the author says that "whatever the type of book the would be refractionist uses it cannot be insisted upon too strongly that the art of refraction cannot in any sense be learned by reading" This booklet is divided into six sections and six appendixes, covering eyestrain, refraction accommodation and convergence, the muscle balance clinical methods of examination and spectacles Although the first edition attracted some unfavorable comment it is believed that the second edition will redound to the credit of the author He does not attempt to teach the beginner how to refract but rather counsels him in the art of refraction Sound clinical advice is scattered throughout the pages particularly with regard to the correction of lower errors of hypermetropia and astigmatism The outline of the management of myopia in children is sound Unfortunately the chapter on convergence is not as clearly understandable as are the other chapters The description of the management of muscular imbalances, tropias or phorias shows a clear understanding of the subject, without the fanaticism exhibited by so

many writers on this subject. The chapter on clinical methods of examination is of necessity brief, but it should be either briefer or else of much greater length. In the last section are numerous extremely practical points not to be found in the average textbook. The appendices of optical tables and formulas and official visual requirements are compact and convenient. This is a good work especially for supplementary reading, for the young refractionist.

Catalogue of the Onodi Collection in the Museum of the Royal College of Surgeons of England. By T. B. Layton DSO MS Conservator of the Museum. Sir Arthur Keith M.D. F.R.S. Cloth. Pp. 131 with 54 illustrations. London: Headley Brothers Journal of Laryngology and Otology. Published in conjunction with the Royal College of Surgeons of England. 1934.

The anatomy of the nasal chambers and the cavities accessory to them have been known in a general way to anatomists and to a lesser extent to physicians for many years. In 1882 Zuckerkandl published his 'Normale und pathologische Anatomie der Nasenhöhle.' This publication and the investigations behind it furnished the impetus to the anatomic and clinical work in the succeeding two decades that brought rhinology to its present high state as an art. In 1900 before a meeting of the Society of Hungarian Ear and Throat Specialists, Onodi demonstrated anatomic specimens the study of which was to form the basis of the world famous publications to be brought forth in the next decade. Among these all of which were translated later into English, were 'The Anatomy of the Nasal Cavity and Its Accessory Sinuses,' 'The Optic Nerve and the Accessory Sinuses of the Nose,' 'The Accessory Sinuses of the Nose in Children' and 'The Relations of the Lacrimal Organs to the Nose and Nasal Accessory Sinuses.' In 1903 Kilian published 'Die Nebenhöhle der Nase und ihre Lagebeziehungen zu den Nachbarorganen.' The work of Lothrop, Mosher and Ingersoll and Hanau Loeb in the United States, and of Logan Turner in Great Britain together with that of others in France and other countries carried forward our knowledge in the detailed anatomy and the topographic relationships of the accessory sinuses, so that by about 1915 the fund of knowledge was about as complete as it is today. The present review concerns itself with a catalogue consisting of an atlas of drawings and photographs made from specimens of that part of the Onodi collection purchased from Professor Onodi's son, Dr Stanislaw Onodi by a number of British medical men and presented by them in turn to the collection of the Royal College of Surgeons. Descriptions of all the specimens in the collection are present in this publication. Many of these were selected for illustration. A preface by T. B. Layton consists of an interesting discussion of some of the problems in nomenclature that have arisen concerning the detailed anatomic features in this field. Rhinologists should get much pleasure from a perusal of this work and a study of its fine illustrations.

Illustrations of Regional Anatomy. By E. B. Jamieson M.D. Senior Demonstrator and Lecturer Anatomy Department University Edinburgh. Section I. Central Nervous System. Section II. Head and Neck. Section III. Abdomen. Section IV. Pelvis. Section V. Thorax. Paper. Price \$8 per set. 203 plates. Baltimore: William Wood & Company. 1934.

These illustrations are reproductions of the drawings made by Professor Jamieson in his lectures in the department of anatomy of the University of Edinburgh. Many of them are colored, and they are loosely bound in five sets so that any individual plate is readily detachable. The sets are grouped as follows: central nervous system, forty-eight; head and neck, sixty-one; abdomen, thirty-seven; pelvis, thirty; thorax, twenty-seven. Any accurate drawings of dissections or any well devised anatomic diagrams repay study. They convey much more information than verbal descriptions in much less time. After one careful dissection has been made they constitute an exceedingly valuable method of rapid review. Thus the atlases of Spalteholz, of Toldt and of Sobotta are of the greatest help to students and physicians. There is no royal road to a knowledge of gross anatomy but such illustrations come closer than anything else to providing one. It is clear that the more drawings of different preparations from different points of view there are available the better is this method of study and review. These drawings of Dr Jamieson do not duplicate those of the atlases in ordinary use. Many are somewhat

diagrammatic, but they are nevertheless true and a reliable means of instruction. Students in countries other than Great Britain will regret somewhat the fact that the labels on all these illustrations are in the local British terminology instead of in the internationally familiar terms of the B.N.A. While the illustrations will be of value to students and physicians everywhere, one can readily understand that they are especially interesting to graduates of the medical schools of the University of Edinburgh, for whom they carry many associations and so constitute an especially valuable means of recalling the knowledge acquired in the dissecting laboratories and lecture rooms of that university.

The Abbey of Evolayne. By Paule Ragner. Translated from the French by Samuel Sloan. Cloth. Price \$2. Pp. 302. New York: Harcourt Brace & Company. 1934.

This novel tells the story of the conversion to Catholicism of a surgeon and of the mental reaction of his young wife to the loss of her husband. The book has in it little of specific medical interest except so far as relates to the mental attitude in conversion. The volume seems to elucidate quite satisfactorily the tenets of the Catholic Church and it has been recommended by the Catholic Book Club.

Female Sex Perversion. The Sexually Aberrated Woman as She Is. By Maurice Childekel M.D. With a foreword by Dr S. Wolman Associate in Medicine Johns Hopkins University. Cloth. Price \$6. Pp. 331 with 10 illustrations. New York: Eugenics Publishing Company. 1935.

This volume is essentially a brief outline of various forms of sex perversion with thumbnail case reports apparently taken from the practice of the author and also from the records of hospitals in Baltimore. It offers also a bare indication of the Freudian conceptions in relationship to such perversions.

Medicolegal

Dental Practice Acts—Appointments to Board Limited to Nominees of Dental Association.—The Tennessee state board of dental examiners revoked the license of Prosterman to practice dentistry and he brought suit in the chancery court, Hamilton county, to have the order of revocation set aside. The court after reviewing the evidence, entered a decree suspending Prosterman's license for thirty days. Both the board and Prosterman appealed to the Supreme Court of Tennessee, the former contending that the chancery court exceeded its authority in modifying the order of the board, the latter protesting that his license should not have been suspended at all.

Prosterman, said the Supreme Court, was entitled to a trial de novo and, under the laws of Tennessee, the chancery court had authority to pass on the facts and modify the order of the board. The Supreme Court sustained the finding of the chancery court that Prosterman had falsely advertised that he had twenty years' experience in all lines or branches of dentistry. Prosterman himself admitted that he had had only ten years. The Supreme Court found misleading a representation made by Prosterman to prospective patients that he was a Dentist formerly Professor and Dean Southern Dental Institute Atlanta, Georgia. Prosterman sought to justify the representation by testifying that he had at one time organized a concern by this name, in Atlanta, which he operated a short time in connection with his dental office there. But, the court said the organization was little more than a name. Prosterman himself testified that he employed no instructors in the so-called institute, that he was the only dentist connected with it. We think, said the Supreme Court it is too plain for argument that such a situation did not justify his holding himself out as formerly Professor and Dean Southern Dental Institute. "Professor" of an "institute," said the court implies a position of importance and recognition by others of capacity. The term "dean" clearly suggests an office of responsibility, and definitely denotes a group situation. It is a misleading misnomer if applied to a situation where but one person is engaged, acting for himself and directing only his own individual activities.

Prosterman further challenged the constitutionality of the dental practice act, specifically complaining that the group from

which the governor may appoint members of the board of examiners is limited, by statute, to such dentists as shall be recommended for appointment by the state dental association. While the practice of dentistry, said the court, is a property right, we do not understand that this is true of membership on the state dental or other appointive boards. The right of every qualified dentist to practice his calling provided he does so within the law, is safeguarded by the dental practice act, and the courts are open to all for relief in case the board of examiners appointed by the governor acts arbitrarily or illegally. We find, concluded the court, no constitutional difficulty with this act. The decree of the chancery court suspending Prosterman's license for thirty days, was affirmed.—*Prosterman v Tennessee State Board of Dental Examiners (Tenn.)*, 73 S W (2d) 687

Abortion, Criminal Fact of Pregnancy Need Not Be Proved—The defendant-physician was convicted of performing a criminal abortion and appealed to the Supreme Court of Washington.

The burden was on the state, said the Supreme Court, to prove that the curettement was not necessary to preserve the woman's life. The evidence, continued the court, established the fact that the woman made unsuccessful attempts to commit an abortion by taking drugs and that she started out to find and did find, a physician who would perform the operation. There was ample competent evidence, in the opinion of the court that the defendant-physician operated on a healthy woman at her request, to procure an abortion and that she died in consequence thereof. The inference from the evidence, the court said, was irresistible that the operation was not necessary to preserve the life of the mother.

The trial court correctly charged the jury, the Supreme Court said, that it was not necessary for the state to prove that the woman was actually pregnant. Under the Washington statutes (Rem Rev Stat sec 2397), one who believing her to be pregnant, uses instruments or other means on a woman for the purpose of producing an abortion, or induces the woman to use an instrument or other means for such purpose, unless the operation is necessary to save the woman's life is guilty of manslaughter if she dies as a result of such operation, even though the woman is not in fact pregnant.

The Supreme Court could find no reversible error in the record and therefore affirmed the judgment of the trial court.—*State v Martin (Wash.)* 34 P (2d) 914

Hospital, Charitable Liability for Injury to Patient—The plaintiff fractured her leg and was taken to the defendant hospital for treatment. While the fracture was being set it was alleged, sparks emitting from a defective fluoroscope in use ignited gases and the plaintiff was injured from a resulting explosion. The plaintiff sued the hospital and when the trial court directed a verdict for the defendant, she appealed to the court of appeals of Ohio, Lucas County.

The defendant contended that it was a charitable corporation and was not for that reason liable. No claim was made in the case, said the court of appeals, that the hospital failed to use ordinary care in selecting and retaining any employee by whose carelessness or incompetence the plaintiff was injured. Manifestly, continued the court if the testimony in the case was true the hospital was being maintained and operated as a public, charitable institution and that fact constituted a complete defense to the plaintiff's suit. The plaintiff contended, however, that the trial judge had no authority to direct a verdict, and that the credibility to be given to the testimony should have been submitted to the jury. The burden rested on the defendant, said the court, to prove that it was a public, charitable organization and while this burden was met by the testimony of only one witness, his testimony was not disputed. There was nothing in the record tending to attack his credibility. Under the circumstances, said the court it was the duty of the trial court to direct a verdict for the defendant. The judgment of the trial court for the defendant was therefore affirmed.—*Walsh v Sisters of Charity of St Vincent's Hospital (Ohio)* 191 N E 791

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below

Essential Shrinkage of Conjunctiva in Epidermolysis Bullosa Dystrophica—Cohen and Sulzberger report the case of a 7 year old boy with the combination of atypical acquired epidermolysis bullosa dystrophica with ocular lesions. The cutaneous lesions were suggestive of both dermatitis herpetiformis and erythema multiforme. The ocular lesions involved both eyes and the acute exacerbations of the cutaneous and ocular conditions frequently occurred at about the same time. This, in addition to their clinical and histologic similarity, led to the conclusion that the ocular and cutaneous lesions were manifestations of the same underlying disease process. The presence of phlyctenae in the early course of the ocular lesions was due to the epidermolysis bullosa and the shrinking and scarring of the conjunctiva as well as the symblepharon were probably the result of the tendency to vesicle formation and the atrophying and scarring processes such as were present in the skin in this case. The necrotic corneal ulcer together with the formation of granulation tissue on its surface were probably the result of the epidermolysis bullosa in the conjunctiva or the cornea itself. The fissure formation between the epithelium and the connective tissue of the conjunctiva and the absence or diminution of elastic tissue fibers in the conjunctiva coincide with the histologic observations in cases of epidermolysis bullosa. The cutaneous and ocular lesions were exaggerated by the internal administration of iodides. Patch tests with iodides and bromides gave positive reactions twice and produced bullous eruptions. The etiology of the condition is unknown, the treatment is inadequate, and the prognosis as far as the eye

is concerned, is grave. In this case one eye had to be removed and the other is showing a gradual increase of the pathologic process. Instillations of olive oil are being used. Injections of neosphenamine seem to have succeeded in bringing the cutaneous process to a standstill and in improving the general health of the patient. These injections are being continued.

Unsaturated Fatty Acid Deficiency—Oncken observes that until recently fats were not considered essential elements of the diet from an energy standpoint, but the work of the Burrs and of McAmis Anderson and Mendel discloses a new deficiency disease of utmost importance to a newer interpretation of many symptoms heretofore vague and of unidentified origin. Careful experiments showed that, if all neutral fat was excluded from the diet but compensating amounts of fat-soluble vitamins were returned in the form of essentially nonfatty concentrates, animals failed to grow properly. Before the animals become moribund, supplementing the diet with a small amount of linoleic or linolenic acids, or preferably both, results in the complete extinction of all the symptoms. Not only do these unsaturated fatty acids, and perhaps others, completely cure the fat deficiency symptoms but, if they are contained in the diet, they prevent the appearance of the deficiency syndrome. The normal function of the liver is in part concerned with the desaturation of fats the better to meet the requirements of the various cells of the body abounding in unsaturates, and contemporary food trends, through the large scale introduction of vitamin-depleted fatty acid extinguished fat supplies, violate and oppose the physiologic activities of the body. In some instances the substitution of liquid petrolatum for fat has taken place. Added to the proved vitamin-depleting property of liquid petrolatum about which innumerable references have appeared and its absolute valueless nutritive property due to its lack of absorption by the organism, there seems to be no need to the lurking carcinogenic property of liquid petrolatum, which has been repeatedly mentioned in medical literature but with equal regularity ignored. This perverted fat supply, fed liberally to the children and adults of a nation in place of the former vegetable oils expressed naturally, make the results of the Burrs take on a new significance.

Treatment of Chronic Typhoid Carriers—Gulbrandsen studied the effects of repeated roentgen exposures over the region of the liver in chronic fecal *Bacillus typhosus* carriers. Twelve carriers have been under observation. The period over which they have been known to be carriers varies from two to twenty-five years. In two instances there was no history of clinical typhoid. All were free from gallbladder or hepatic

disease, but in one patient the gallbladder had been removed five years before because of stones. From three to sixteen roentgen exposures were given over the region of the liver during the past two years. One third of the cases have been rendered free from *B. typhosus* for periods varying from ten to twenty-four months, one third have evidenced a reduction in the total *B. typhosus* output in the stool, and the others showed no change. The results obtained are encouraging enough to warrant further study, and the author recommends roentgen therapy as a possible means of controlling the carrier state.

Some Iron Containing Foods O. W. Bethea New Orleans—p. 624

Recognition and Treatment of Primary Syphilitic Lesions—Culpepper and Howles contend that the diagnosis of early syphilis is a laboratory and not a clinical procedure. They studied ninety cases, which represent all the positive primary lesions diagnosed by dark field examination in the hospital and clinic over a period of nine months, including genital and extragenital lesions. They endeavored to learn the effect of systemic antisyphilitic treatment on the dark field as well as its effect on the Wassermann reaction, using bismuth potassium tartrate in butyn, insoluble form, injected intramuscularly in doses of 2 cc each and neoarsphenamine intravenously in doses of 0.3 Gm. The bismuth preparation produced a negative dark field in twenty-two cases within an average of three and one-half days but it was still positive in four cases from one to eight days later. With neoarsphenamine ten cases were dark field negative within twenty-four hours and one was still positive after twenty-four hours and one dark field examination had changed from 3+ to 1+ within twenty-four hours. This comparison is considerably in favor of neoarsphenamine. In the Wassermann check, sixteen cases never became positive and six cases became negative after an average of four bismuth injections.

Effect of Pregnancy Urine on Conception in Rats—McGee injected white female immature rats with two separate hormones and mated them when 100 days of age. Twenty received varying amounts (from 6 to 90 rat units) of a pregnancy urine hormone. Sixteen received from 6 to 120 rat units of a pituitary gland hormone. He observed that the administration of small amounts of pituitary gland hormone and pregnancy urine hormone to immature rats produced larger litters. Large and medium doses apparently inhibited conception. Microscopically it was found that ovaries from rats receiving small doses of the hormones were stimulated to produce many primordial follicles and follicle cysts. The ovaries from rats that had received large and medium doses were almost entirely replaced by lutein tissue. This undoubtedly reduced the fertility of the animals either by blocking ovulation, changing the ovum in some way so that its development was retarded, or by stimulating most of the primordial ova to develop very rapidly over a short period of time. The two hormones do not cause absolute sterility but inhibit fertility. This was proved by the fact that only one third of the animals became pregnant.

Curability of Cancer—Judd and Hoerner believe that the treatment of cancer should be approached with more enthusiasm, for knowledge of malignant disease has increased steadily. One of the most useful observations that has been made is that the disease starts as a single focus. For this reason, removal of the tumor should afford complete relief if it is accomplished while the disease is in a fairly early stage. This is the feature that makes the disease curable. Not infrequently in performing an exploratory operation, one observes lymph nodes that appear to be involved, and they often are in a situation which precludes carrying out excision with a reasonable degree of safety. Such lymphatic structures, or even a distant nodular growth in the liver, may be of an inflammatory nature. Thus, the presence of a nodule of indeterminate nature should not contraindicate removal of the primary growth if this can be accomplished satisfactorily. Experience has often shown that after removal of the primary cancer the metastatic lesion may regress or at least remain quiescent for a considerable length of time. The grading of malignant tumors has been of great assistance in the treatment of cancer. The cellular structure is one of the chief factors in determining the nature and extent of the surgical procedure and the benefit to be derived from irradiation. Radium and roentgen therapy are no longer used merely for palliative purposes when lesions are in hopeless situations but are valuable adjuncts to the treatment of cancer, chiefly because the principles for their correct usage are getting to be understood. The best results from irradiation alone are limited to certain types of cancer. With other types, surgery supplemented by irradiation will give the patient the best opportunity for complete and permanent relief from the disease.

The Aronson Streptococcus.—Griffith obtained the Aronson streptococcus (Neufeld type), which Lancefield places in a group containing chiefly streptococci of bovine origin, from human throats, but there was no evidence in any instance that it was producing disease, and it seems probable that it is not pathogenic for man. The results of his investigation of this strain are in agreement with those of Yoshoka, Killian and Lancefield. There are in existence other laboratory strains designated Aronson streptococcus. These have been found to exhibit specific characters identifying them with *Streptococcus pyogenes*. It is proposed that the name *Streptococcus Aronson* should be confined to strains possessing the characters of Aronson N (the strain obtained from Neufeld).

Toxic Fractions of Scarlatinal Streptococci.—Among a series of strains of hemolytic streptococci from thirty-five cases of scarlatina in the first week of illness Green found fourteen to correspond with one or another of Griffith's serologic types I, II, III and IV. Of these fourteen strains twelve were selected for further examination and found to yield a true heat-labile exotoxin completely inactivated by heating for thirty minutes at 100 C. The concentration of exotoxin in 0.5 per cent dextrose broth cultures was at a maximum after an incubation of ninety-six hours and thereafter on further incubation progressively diminished. No qualitative difference could be detected among the exotoxins from the different strains the test criterion being the dermal reaction in Dick positive persons. Cultures of organisms of the same or different serologic type isolated from the same source and thereafter similarly treated yielded approximately equivalent amounts of exotoxin. Broth culture filtrates also contained an acid-insoluble toxic fraction, the concentration of which increased with the age of culture and which appeared to be identical with a similar acid-insoluble fraction derived from an alkaline extract of washed bacterial bodies. This acid-insoluble fraction was extremely resistant to heat three hours of boiling at 100 C. being required for inactivation. In this respect the acid-insoluble fraction corresponded to the bacterial endotoxins. The acid insoluble fractions from cultures of the same serologic type produced equivalent skin reactions in susceptible persons. These fractions from cultures of different serologic types differed qualitatively as determined by skin reactions. The reaction to crude filtrate was found to be the sum of the reactions to the exotoxin fraction and to the acid-insoluble fraction present in the filtrate.

Hereditary Syphilis of Kidneys.—Late hereditary syphilis of the kidneys is a rare disease, according to Valverde. In all patients in whom a hematuria of doubtful cause is present, syphilis of the urinary apparatus must be considered. Careful history and the presence of a positive Wassermann reaction are important diagnostic aids. The results of antisyphilitic treatment are of decisive value. Hematuria of this nature is, however resistant to treatment, and an exacerbation may occur at the beginning. Antisyphilitic medication must not be abandoned because of this occurrence.

Meningo-Encephalitis in Mumps.—Wegelin reports a case in which a boy, aged 8, several days after contracting mumps, developed a severe meningo-encephalitis with typical changes in the cerebrospinal fluid (lymphocytosis) and with paralysis and convulsions. The disease terminated fatally on the eighteenth day. Histologic examination revealed meningitis and encephalitis with lymphocytic infiltration partly of a hemorrhagic character and connected with destruction of nerve fibers, severe perivascular proliferation and fatty degeneration of the glia cells. The author thinks that these changes were the direct effects of the filtrable virus of mumps.

Value of Quinine in Obstetrics.—According to Hadjileff the ecbolic action of quinine was first discovered in connection with the quinine therapy of malaria, for it was observed that pregnant women who were treated with quinine for malaria developed genital hemorrhages and occasionally abortion resulted, and that quinine increased the menstrual flow and produced an increase in labor pains. The author maintains that the ecbolic action of quinine involves no danger, if it is given in small doses. It reduces the intervals between the uterine contractions and intensifies and prolongs the contractions. It can be employed during all stages of the process of birth, particularly during the period of dilatation and of expulsion of the afterbirth. It has been found effective in atonic hemorrhages before and after the expulsion of the placenta. However, quinine is not suited for the induction of labor. Quinine can be used as an abortifacient and during premature birth and surgical delivery. The combined administration of quinine and pituitary extracts has been proved efficient in many obstetric clinics. The combination preparation can be used also for inducing labor in pregnancies that have continued past term.

Large Hydatid Cyst of Douglas Pouch A Ventura—p 557

Intravenous Vaccine Treatment of Undulant Fever.—Guigni found that pronounced febrile reactions may be obtained in patients with undulant fever by injecting antimelittensis vaccine intravenously. He began with several injections of from 5 to 10 million micro-organisms. After an interval of from two to five days the dosage was increased to from 50 to 300 million micro-organisms. No less than eight and no more than ten injections were given to each patient. The injections were well tolerated in all cases and were not dangerous even when

the patient was in a grave condition. After a pronounced reaction the fever subsided in all patients and the size of the liver and spleen was rapidly reduced. In some patients a dose of from 200 to 300 million micro-organisms was required to obtain the necessary reaction. Despite the number of injections given, only one or two produced the greatest febrile reaction. When the vaccine was injected during defervescence, the reaction was slow. The author suggests the use of high doses because of their ability to reduce the fever and to combat the disease itself, provided there are no contraindications, such as organic lesions of vital organs. Cure was rapid and constant.

Panaritiums of Bones, Joints and Tendons E Hudnesh—p 264

Kaufmann's Diuresis Test of Cardiac Function—The technique of the test, according to Frey, is as follows. The patient is asked to maintain a horizontal position in bed to drink 150 cc of fluid hourly and to pass urine every hour. The test is begun in the morning one or two hours after awakening in order to avoid the physiologic diuresis. At the end of four hours the foot of the bed is raised 25 cm and the test resumed after two hours. The hourly passage of urine is measured and its specific gravity determined and the amounts passed in the horizontal position and with the lower limbs raised are compared. Kaufmann states that the elevation of the feet in healthy subjects does not effect diuresis. The amount of urine is likewise not increased in patients with high grade cardiac edema. Cardiac patients without manifest edema but suspected of having latent edema react to the test by an increase in urine excretion. These patients are likewise distinguished by the fact that they absorb hypodermically injected solution of salt more slowly than do normal subjects. The same holds true of renal edema. The test is valuable in recognizing latent edema regardless of its etiology. The author has subjected many patients to the test and considers it valuable in the recognition of latent weakness of the cardiac muscle. A critical attitude toward the test as well as the use of all clinical methods of investigation is a prerequisite for arriving at a reliable estimate of the cardiac function.

Pregnancy Blood in Treatment of Glandular Cystic Hyperplasia—Damm shows that, if hormone therapy is to be employed in glandular cystic hyperplasia which is the result of the persistence of the follicle and of the lack of corpus luteum formation either the corpus luteum hormone can be directly substituted (to effect a cessation of the hyperproliferation and induce a secretory phase) or the pituitary luteinization hormone can be administered to cause bursting of the persistent follicle and thus influence the formation of the corpus luteum. Although the substitution therapy usually counteracts the bleeding the subsequent menstruations are never normal, for as a rule there develops a shorter or longer amenorrhoea, after which the patient has a relapse. The stimulation therapy has the disadvantage that the pituitary luteinization hormones must be given in large quantities and that during storage the preparations quickly lose their efficacy. The author resorted to the intravenous injection of pregnancy blood in patients with glandular cystic hyperplasia. He administered 400 cc of pregnancy blood and, in view of the results he obtained with this treatment he concludes that the administration of pregnancy blood is the ideal treatment for

glandular cystic hyperplasia not only because a strong influence is exerted on the persisting follicle but also because the intravenous injection permits the administration of larger and consequently more effective doses of hormone than does the intramuscular or subcutaneous injection of the hormones.

*Radical Treatment of Pulmonary Suppuration S I Spasokukotskiy and S G Gyskuni—p 499

Walled-Off Perforations of Gastric-Duodenal Ulcer—According to Vikker, spontaneous closure of a perforated ulcer occurs not infrequently. The closure of the perforation is favored by certain conditions, among them absolute rest of the patient. A walled off perforation presents a fairly definite clinical picture. Boardlike rigidity of the right upper abdominal quadrant following an acute attack of pain in a man with a history of ulcer is characteristic of the condition. The rather frequent mild form of closed perforations is usually diagnosed as acute cholecystitis. Operative intervention is indicated in all clear cut cases of closed perforations in the first twenty-four hours especially if the pain persists. A case of closed perforation seen in a late stage requires an individual approach, as in any late case of peritonitis. In all cases suspected of closed perforation a long period of rest in bed and a dietetic regimen are obligatory.

Radical Treatment of Pulmonary Suppuration—Spasokukotskiy and Gyskuni report a series of ninety-nine cases of pulmonary suppuration. Of these, eighty-six were postpneumonic seven postoperative and embolic one malignant, and one developed on the basis of an ecchymococcus, one on the basis of actinomycosis and one in a congenital cyst of the lung. The authors advocate the radical method of treatment. Suppuration of lung tissue is complicated as a rule by pleuritis, which is erroneously considered the primary disease. They urge a two step operation because one cannot be sure of formation of limiting adhesions even in cases of six months duration. The two-stage method with tamponade in between is urged for two reasons to prevent infection of the pleural cavity as well as the formation of a gas phlegmon of the subcutaneous connective tissue. The authors stress the efficacy of blood transfusion in the preoperative treatment.

Traumatic Periarthritis with Peculiar Course Case H Heidemann—p 311

Bovine Pulmonary Tuberculosis—Tobiesen and his co-workers report that ten of the twenty-six patients suffering from bovine pulmonary tuberculosis and treated in Copenhagen hospitals from 1931 to 1933 were children less than 5 years of age no patient was more than 32. Most of the cases appeared to be of alimentary origin, and in no case was there evidence of even probable infection from another person. The lung processes as revealed on roentgen examination did not seem to present any peculiarities distinguishing them from the characteristic changes seen in the different age groups of pulmonary tuberculosis in general. In eighteen cases tubercle bacilli were cultivated only from the stomach lavage water. Six patients died before April 1934 of these, three were less than 5 years of age two were between 5 and 15 and one was more than 15.

Those diseases which medicines do not cure, iron
(the knife) cures, those which iron cannot cure, fire
cures, and those which fire cannot cure are to be reck-
oned wholly incurable

This last of the hippocratic aphorisms might be taken
as the source of the mandate accepted by some of the
advocates of therapeutic hyperpyrexia, for it is their
somewhat optimistic opinion that certain diseases which
medicines or surgery cannot cure may be cured in the
fires of fever therapy and that those which are not
cured thereby are at the moment incurable. Since the
days of Hippocrates, fever has been a major concern
of physicians, most of whom have looked on it as a
defensive mechanism against disease. An altered regard
for fever was initiated by Claude Bernard, Virchow
and others, who demonstrated supposedly harmful phys-
iologic and pathologic reactions thereto.¹ Thus began
the era of apyrexia by medical and physical means.

That fever, however, must serve some very useful
purpose, or nature would not have retained it so
tenaciously as a reaction process to invasion of harm-
ful substances was the conclusion of Welch² and
others who, in the past forty years, have fostered a
return of the former idea of fever's beneficence. The
current development of fever therapy is a testimonial to
the wide acceptance of their views. Under certain
conditions, and within certain limits, hyperthermia is a
state not to be prevented but to be fostered. Various
methods for its more or less safe production are being
increasingly elaborated. The day of pyretotherapy, of
"friendly fever," is already well advanced.

METHODS OF PRODUCING THERAPEUTIC FEVER

Many old and new methods are being advocated for
fever therapy. Since the sixteenth century, curative
effects in syphilis and various forms of rheumatism
have been ascribed by the Japanese to frequent bath-
ing in very hot volcanic water. The temperature of
the water being from 113 to 128 F, it has been esti-

mated that fevers of from 103 to 105 F were produced
thereby.³ It has become the fashion to regard the
febrile reactions of foreign protein therapy as the mod-
ern forerunner of fever therapy. Some ascribed the
benefits of such reactions to other factors than the
fever produced and tried to avoid the latter. As a
result of Wagner-Jauregg's success with malarial
therapy in syphilis, however, the febrile component of
analogous reactions has regained prestige, and the use
of dead organisms (*Bacillus coli* or *typhosus*) having
become supplanted by the use of live (malarial) organ-
isms, other febrile reactions, which were presumably
more benign, were suggested: those of rat bite fever
and relapsing fever. While certain definite results have
been obtained, these various methods have the disad-
vantage that their reactions, once initiated, are not
always entirely controllable. Hence the modern view
favors a return to physical, in place of bacterial,
methods of producing fever.

Steps in the development of pyretotherapy by phys-
ical means, as traced by several,⁴ include the use of hot
baths by Philips⁵ (1883), by Schamberg and Tseng⁶
(1927) and by Mehrtens and Pouppart⁷ (1929), of
hot air by Rosanoff⁸ (1927) and Walinski⁹ (1928),

RATIONALE OF FEVER THERAPY

It has long been noted that the altered conditions incident to some intercurrent, unrelated, generally febrile disease are at times antagonistic to the continuation of a primary illness. Authentic instances are recorded wherein a patient, with for example a previously progressive chronic arthritis, has rather suddenly experienced a prolonged remission, at times a cure the unexpected gift of an otherwise unwelcomed intercurrent disorder. It has been observed clinically and experimentally that the lowering of body temperature diminishes the resistance of a host, human or otherwise, to certain bacterial infections. There is experimental evidence to support the contention that high temperatures exert a bactericidal and bacteriostatic effect on certain germs in vitro. These observations provided the impetus for a trial of hyperpyrexia in the treatment of various diseases, including arthritis.

PHYSIOLOGIC REACTIONS TO FEVER THERAPY

Regardless of the method used, whether diathermy, radiotherapy, hot baths or heated cabinets, the resultant hyperthermia is characterized by more or less identical physiologic effects. These have been summarized by Fatherree¹⁹ and others²⁰ as follows:

Bacteriolysis—Gonococci generally at a temperature of from 106 to 107 F (Carpenter Boak Mucci and Warren²¹).
Streptococci no data.

Blood Flow—Pulse rate increased up to from 130 to 150 beats per minute (Bazett,²² Bierman,²³ Bishop, Horton and Warren²⁴).

Circulatory rate increased (Bazett,²² Bierman,²³ Kissin and Bierman²⁵).

Cardiac output increased minute volume output (Bierman²³).

Blood pressure initial rise, subsequent fall (Bierman and Fishberg,²⁶ Bishop, Horton and Warren²⁴).

Blood volume no change, or slight concentration (Bierman and Fishberg,²⁶ Bischoff, Long and Hill²⁶).

Viscosity no change, if intake is encouraged (Bierman and Fishberg,²⁶ Tenney²⁷).

Nail-bed capillaries increased in number and size (Tenney²⁷).

Blood Cellular Elements—Erythrocyte count generally no change (Tenney²⁷).

Erythrocytes, sedimentation rate little or no change (Nicholls, Hansson and Stainsby²⁸), increased (Tenney,²⁷ King,²⁹ Moen, Medes and Chalek³⁰).

Leukocyte count initial fall, subsequent rise to 15,000 per cubic millimeter (Bierman,²³ Warren and Wilson³¹).

Leukocytes increased rate of phagocytosis (Warren and Wilson³¹).

Blood Chemistry—Non-nitrogenous elements (urea, uric acid, creatinine) no change (Karr and Nasset³²) or slight increase (blood concentration), (Neymann and Osborne,³ Simpson, Kisligh and Sittler¹⁸).

Sugar, phosphorus, plasma lipoids, serum calcium no change or slight increase (blood concentration, Neymann and Osborne,³ Simpson, Kisligh and Sittler,¹⁸ Bierman,²³ Walinski,³³ Bischoff, Maxwell and Hill,³⁴ Bischoff, Ullmann, Hill and Long,³⁵ McQuarrie and Stoesser,³⁶ Hopkins³⁷).

Inorganic phosphorus converted to organic form (Bischoff, Maxwell and Hill,³⁴ Bischoff, Ullmann, Hill and Long³⁵).

Serum protein no change (Moen, Medes and Chalek³⁰) or increase (Karr and Nasset³²).

Acid-base equilibrium altered in the direction of slight alkalosis (Bischoff, Long and Hill,²⁶ Bischoff, Maxwell and Hill,³⁴ Bischoff, Ullmann, Hill and Long,³⁵ Hopkins³⁷).

Chlorides may be markedly dropped (Simpson³⁸).

Oxygen content and capacity of venous blood increased (Bischoff, Maxwell and Hill,³⁴ Bischoff, Ullmann, Hill and Long,³⁵ Goldfelder³⁹).

Carbon dioxide combining power decreased (Bischoff, Long and Hill,²⁶ Bischoff, Maxwell and Hill,³⁴ Bischoff, Ullmann, Hill and Long,³⁵ Hopkins,³⁷ Nasset, Bishop and Warren⁴⁰).

Blood-Immune Bodies—Agglutinins variable data—rise (Reimann¹) or fall (Ecker and O'Neal⁴¹).

Complement no change (Jung and Day⁴²), reduced (Bierman and Fishberg²⁰).

Opsonic index no change (Jung and Day⁴²).

Gastric Secretion—Loss of chlorides (Simpson, Kisligh and Sittler¹⁸ Simpson³⁸).

Sweat—Loss of from 18 to 26 Gm of sodium chloride in from 3 to 4 liters of sweat in each session (Simpson, Kisligh and Sittler¹⁸).

Increased lactic acid content (Bierman and Fishberg²⁰).

Urine—Amount generally temporary oliguria (Karr and Nasset³²).

Reaction Unchanged or slightly alkaline (Karr and Nasset³²).

Metabolic Rate—Increased 7 per cent per degree of fever (Berris,¹⁷ Neymann and Osborne,²⁰ Bierman,²³ Tenney²⁷).

Electrocardiogram—Contractions of lowered voltage (Bishop, Horton and Warren,²⁴ Wiggers and Orías⁴³).

Many of the reactions are of little or no importance from the standpoint either of resultant discomfort or of relief. The benefits of fever therapy presumably arise from (1) a direct bacteriolytic or bacteriostatic effect due to the influence of heat itself on bacteria (without necessarily implying formation of immune

bodies), (2) an indirect bacteriolytic or bacteriostatic effect resulting from increasing formation or mobilization of immune bodies, (3) a local effect from vasodilatation, providing an augmented blood supply to inflamed tissues, and (4) a general effect from the heightened metabolism incident to fever. An arthritic patient may be helped by any one of these factors acting alone or in combination. It must be admitted that data regarding all these factors, particularly the second, the augmentation of immune bodies, are meager and contradictory. Until more work is done, conclusions are somewhat presumptuous.

Some of the reactions to fever therapy are of no significance as far as benefits are concerned but account

Reported Contraindications to Fever Therapy—The following conditions have been considered to be contraindications to fever therapy: advanced age, myocardial and renal insufficiency, marked hypotension, active tuberculosis, aortic aneurysm, rapidly progressive late neurosyphilis, and abnormal conditions of the skin which interfere with adequate sweating.

THE APPLICATION OF FEVER THERAPY TO THE ARTHRITIDES

Modern methods of fever therapy were applied to arthritic patients about three years after the initial use of such methods in syphilis. The results of fever therapy for chronic infectious (atrophic) arthritis were

for unpleasant side-actions. Most notable of these is that reported by Simpson and his colleagues ⁴⁴ marked loss of chlorides from blood and tissues. Patients may lose from 18 to 26 Gm. of chlorides in the 3 to 4 liters of sweat exuded during each session of fever. Thus the amount of chloride lost in sweat may exceed its total quantity in the blood. As a result, free hydrochloric acid disappears from the gastric juice and the blood chlorides may fall 40 mg. or more (100 mg. in one case) per hundred cubic centimeters of blood. Simpson feels that this loss of chlorides is largely responsible for the symptoms of exhaustion, nausea, vomiting, abdominal cramps and muscular twitching that sometimes occur during or after fever sessions, and that these symptoms can be practically eliminated by supplying large quantities (from 2 to 4 liters) of chloride-containing fluids, such as iced 0.6 per cent saline solution orally.

first reported in 1931 by Markson and Osborne ⁴⁵ results for gonorrheal arthritis were first reported in 1932 by Carpenter and Warren ⁴⁸ and by Bishop, Horton and Warren ²⁴. Since then, fever therapy has also been used in a very few cases of senescent (hypertrophic) arthritis, gouty arthritis, traumatic arthritis, and neuritis, including sciatica, myositis (fibrositis) and bursitis.

FEVER THERAPY IN CHRONIC INFECTIOUS (ATROPHIC) ARTHRITIS

Fifteen reports, by ten groups of workers, on experiences with fever therapy in chronic nonspecific infectious (atrophic, rheumatoid, proliferative) arthritis have appeared since 1931. Methods and results are

⁴⁴ Simpson, Kulig and Sittler ¹ Simpson ²³

summarized in table 1. In some reports data are meager and are frankly based on preliminary impressions.

Method—Production of fever by means of diathermy ("superdiathermy") was the method used by four groups of workers.⁴⁷ Radiothermy was used by Tenney.²⁷ Of those who have used more than one method, diathermy is preferred to radiothermy by Carpenter and Warren⁴⁰ at Rochester, N. Y., whereas Simpson and his co-workers⁴⁸ at Dayton, Ohio, prefer air conditioned cabinets to radiothermy. Heated cabinets were used by Berris.¹⁷ Recently, Osborne and Markson⁴⁹ and Merriman, Holmquest and Osborne⁵⁰ have substituted the use of the "inductotherm" for diathermy.

Those who favor diathermy do so because of the presumably greater expense of radiothermy and the danger of burns from arcing inherent in the latter

expensive and cumbersome apparatus, there is a tendency on the part of some to be content with even simpler methods and to advocate the induction of fever by multiple electric pads and heating blankets,⁵¹ or by long immersion in a hot tub. Thus Coulter,⁵² who primarily favors hyperpyrexia by diathermy, uses hot baths to lower the cost of treatments.

The bath water is at an initial temperature of 110 F, except for nervous patients, when it is 106 F. The patient generally remains in the bath one hour. When his temperature has risen to 104 F, the temperature of the bath is reduced to this temperature, 104 F. At the end of one hour in the tub, the patient's fever is maintained for several hours by blankets and hot water bottles.

Coulter considers this method of producing fever simple but not as comfortable as by diathermy, and fever is not maintained as long. Kovacs'⁵³ plan of hyperpyrexia baths is essentially similar to that of Coulter.

Dosage of Fever—The recommended "dosages" of fever have differed considerably (fig 1). Some believe that two, four or six hours at from 102 to 103 F will suffice for one session, for example, King,²⁹ who favors diathermy, Speed,⁴⁷ who favors diathermy, and Berris,¹⁷ who favors heated cabinets. Others recommend from five to eight hours at 104 to 105 F. Markson and Osborne⁴⁵ (diathermy), Nicholls, Hansson and Stainsby²⁸ (diathermy), and Simpson⁴⁸ (heated cabinets). Temperatures above 105 F are recommended for patients with chronic infectious arthritis by but few, such as by Tenney,²⁷ who favors radiothermy. Kovacs'⁵³ believes that such patients do not tolerate well temperatures of more than 104 F.

The great desideratum in fever therapy is to obtain and to maintain a degree of fever that will actually kill, or at least seriously retard the growth of, organisms in vivo and yet be essentially harmless to the tissues of the host. In gonorrheal arthritis, as will be seen later, data on the thermal death time of various strains of gonococci in vitro and in vivo have been determined, and an effective dose of fever has apparently been established. This is not so in chronic infectious (atrophic) arthritis. The cause of the latter disease is of course not yet definitely identified, though it is believed by many to be a streptococcus of some sort, probably of the viridans or hemolytic type. Until information is available concerning the thermal death time of the various arthrotropic streptococci under suspicion, the dosage of fever for this disease can be at the most but guesswork.

Number and Frequency of Fever Sessions—Earlier workers tried to make two or three sessions of fever suffice, when results were frequently unsatisfactory and symptoms continued, the number of sessions was gradually increased, some insisting that from ten to twenty sessions were required.⁵⁴ Recently there has been a tendency to accept the experience of the majority, who favor a total of six to eight sessions of fever as one course of treatment, though some investigators still feel that a smaller number may give as good results. Thus Simpson is of the opinion that two or three treatments, with an interval of one or two weeks intervening, are apparently as effective as a greater number.

SCALE OF DOSAGE FOR FEVER THERAPY

Fig 1—Scale of dosage in fever therapy for gonorrheal arthritis and chronic nonspecific infectious arthritis. The authors estimate dosage in terms of rectal temperature (about 1 degree F higher than the oral temperature). Doses recommended by some investigators are based on oral temperatures; those recommended by others are based on rectal temperatures.

method. This danger can be avoided with care, according to the protagonists of radiothermy, and they insist that patients' reactions to radiothermy are less exhausting and severe than to long sessions of diathermy. Simpson and his colleagues⁴⁸ were quite as able to develop and to maintain the desired levels of fever by means of air conditioned cabinets ("Kettering Hypertherm") as with radiothermy, the use of which they have therefore discarded. As a further reaction to

Sessions have been given by some as often as every two to three days, by others only every seven to fourteen days. The usual schedule is one session twice a week. A second course of fever may be advised if symptoms of arthritis persist after an interval of two or three months.

Results—In considering results reported to date it must be realized that each worker has in general treated only a few patients, only two of the fifteen reports being concerned with more than twenty patients. Percentages of "cures" refer to those patients who were reported as obtaining "complete relief," as becoming "symptom free" for a considerable period of time, or as "cured." "Cures" were obtained by Tenney²⁷ in 25 per cent of sixteen cases, by Berris¹⁷ in 18 per cent of eleven, and by Markson and Osborne⁵⁵ in 21 per cent of nineteen. "Some" of King's²⁰ patients were cured. The results of Markson and Osborne have varied, presumably with experience. In their first report⁴⁸ 33⅓ per cent, or two of six patients, were markedly relieved but none were cured, in their second report⁵⁶ 16 per cent, or three, of nineteen patients were markedly relieved by fever induced by diathermy, and 21 per cent, or four patients, were completely relieved for as long as fifteen to twenty-one months. According to their third report,⁴⁹ 70 per cent of an unstated number of patients were markedly relieved by the use of the "inductotherm" but none were classified as cured.

It would appear that from 25 to 50 per cent of the patients treated in the various series received only moderate relief, and that no relief was obtained in from 13 to 37 per cent of cases reported by some, and in from 50 to 75 per cent of cases reported by others. Particular attention should be given to the reports of the two larger series that of Kohn and Warren,⁵⁶ who treated forty-three patients, and that of Simpson, who treated at least forty patients. No "cures" are reported by either, but 80 per cent of Kohn and Warren's patients obtained some relief (marked or moderate), and a majority of Simpson's patients obtained either marked or moderate improvement.

To others the results of fever therapy for chronic infectious arthritis have been frankly disappointing. Thus, Cecil⁵⁷ believes that the wave of enthusiasm for hyperthermia is not justified. In a limited series (number not stated) no benefit was noted by some, and only a temporary effect was noted by others, in a few cases improvement was apparently permanent. Of twelve patients treated by Nicholls, Hansson and Stainsby,⁵⁸ none were cured and none were markedly relieved. Only 25 per cent (three patients) were moderately relieved and 75 per cent (nine) received no apparent benefit.

Summary of Results—Because several of the investigators have omitted figures, a summary of their total experience cannot be given. Fairly complete data are given (in reports 1, 7, 10 and 13 in table 1) concerning forty-eight cases in which 13 per cent of patients were listed as cured or completely relieved, 18 per cent markedly relieved, 29 per cent moderately relieved, and 40 per cent not benefited. When one adds to these data the figures given in reports 5, 9 and 15 in this table, it would appear that of this total of 147 patients about 7 per cent (ten) were considered

as cured or as completely relieved from the activity of the disease. Sixty-six per cent (ninety-eight patients) obtained variable degrees of improvement and 27 per cent (thirty-nine) obtained no appreciable relief. Of those who were variably improved, probably half or less were relieved markedly, the others were benefited moderately.

One may therefore conclude that of all patients with chronic infectious (atrophic) arthritis concerned in these reports approximately 10 per cent (7 per cent minimum and 13 per cent maximum) became symptom free, about 25 per cent were markedly relieved, about 35 per cent were moderately relieved, and about 30 per cent (27 per cent minimum and 40 per cent maximum) received no benefit. In other words, a third of the patients were markedly or completely relieved and two thirds obtained only moderate relief or none at all.

Experience has been insufficient to determine finally which method of production and what dose of fever are most desirable. The analysis of cases has included but scant data on the duration, extension and degree of activity of the arthritic process under treatment. To date there is no clear cut evidence that results are dependent on one particular method or that a "correct dose" has been definitely established. Similarly, wide differences are apparent in the results by the various methods and doses now employed.

FEVER THERAPY FOR GONORRHEAL ARTHRITIS

Since 1932, nine reports have appeared, from six groups of workers, on the effect of fever therapy on gonorrheal arthritis. An analysis of these experiences is given in table 2. As in reports on chronic infectious (atrophic) arthritis, data at present are meager and incomplete, and the number of patients treated by each group of investigators is small, from two to twelve. The same diversity in methods for producing fever is apparent. Regardless of the method used, the reports indicate that rapid sterilization of the joints and the genito-urinary tract can be accomplished if the patient's temperature can be elevated long enough to reach or exceed the thermal death point of the gonococcus.

Fever Sessions, Dose, Number, Frequency—Some of the handicaps present in the problem of treating chronic atrophic arthritis are not present in the treatment of gonorrheal arthritis. The causative organism of the latter disease is known, and the thermal death time of the organism having been determined, the matter of dosage can be estimated with considerable accuracy and confidence. The thermal death time of fifteen or more strains of gonococci in vitro has been found by Carpenter, Boak, Mucci and Warren²¹ to be about five hours at from 105.8 to 107.6 F. A few strains are more resistant and need the same temperature for longer periods or a higher temperature for shorter periods. Such information is of the greatest help in estimating the dose effective in killing these organisms in vivo. Thus it is recommended by those who have obtained the best results in gonorrheal arthritis that each dose of fever be at least five hours at 106.7 F (reports 1, 2 and 4, table 2). Others have used an approximate dose (from three to five hours at 104 to 106 F).

The majority have found that only one to three sessions of fever of five hours at about 106.7 F are necessary. When smaller doses of fever were used (from two to six hours at 102 to 103.5 F) from four to six sessions were necessary, and even then the results were not as good as when higher temperatures were reached and maintained. Sessions were given every three to seven days.

56. Kohn L. A. and Warren S. L. Preliminary Report on the Treatment of Chronic and Subacute Infectious Arthritis by Artificial Fever. *J. Clin. Investigation* 12: 971 (Sept.) 1933.

57. Cecil R. L. Rheumatoid Arthritis. A New Method of Approach to the Disease. *J. A. M. A.* 100: 1220-1227 (April 22) 1933.

Results—The effects of fever therapy on gonorrheal arthritis have been much more striking than on chronic infectious arthritis. Warren and his collaborators, Carpenter, Bishop, Horton and Wilson,⁵⁸ have reported that for the small number of patients treated by them the results have been "very encouraging." Those treated by Carpenter and Warren⁴⁶ were "usually cured," although in one case there was complete failure after seven hours of heat at 106.7 F. In this case the thermal death point of the gonococcus isolated from the joint was much higher than the amount of fever given the patient. In those treated by Bishop, Horton and Warren²⁴ acute arthritis subsided rapidly, redness and tenderness disappeared, and mobility was gradually restored, chronic gonorrheal arthritis became painless and some mobility was regained.

These gratifying results have been corroborated from several sources. Thus Tenney²⁷ concluded that hyper-

The majority of patients treated have had acute or subacute gonorrheal arthritis but, in addition to Bishop, Horton and Warren,²⁴ Kovacs⁶⁰ has also noted "good results even in stubborn chronic gonorrheal arthritis."

Summary of Results—As data are incomplete, the total number of cases concerned in these nine reports cannot be calculated. Of thirty-three cases mentioned, data on results in twenty-four cases can be tabulated. Of these twenty-four patients with gonorrheal arthritis, apparently twenty-two (92 per cent) were promptly and "completely relieved" or "cured." Failure resulted in only two cases (8 per cent) and was due, as stated, to an inadequate dose of fever.

FEVER THERAPY FOR OTHER FORMS OF ARTHRITIS AND "RHEUMATISM"

Those forms of joint diseases which have so far come within the scope of fever therapy have been

TABLE 2—Reported Results of Fever Therapy in Gonorrheal Arthritis

* Data incomplete
† Method preferred

thermia acts almost as a "specific" for gonorrheal arthritis. He advocates a temperature of 106 F for three to four hours and believes that the thermal death point of the organism is generally about 104 F. Simpson, and his colleagues Kislig and Sittler,¹⁸ who have treated twelve patients, stated that "the results were uniformly successful." Seven of eight patients treated by Atsatt and Patterson⁵⁹ were completely relieved after from one to five sessions of fever, even though the doses of fever were smaller (five hours or less at temperatures not more than 103.5 F) than those deemed necessary by others. Their one patient who was not relieved was admittedly given a temperature that was too low. An inadequate amount of fever was also the probable cause of failure in the treatment by Berris¹⁷ of one patient with "extremely active gonorrheal infection."

chiefly cases of chronic nonspecific infectious arthritis and gonorrheal arthritis. However, certain other types of "rheumatism" have also been similarly treated. There are, of course, many types of arthritis. Aside from arthritis due to specific infections, trauma and gout, the two major types are commonly designated as chronic "infectious" (atrophic, proliferative or rheumatoid) arthritis and chronic senescent (hypertrophic, degenerative or osteo-) arthritis. Differentiation of these two more common types is important, as their course and the prognosis are quite different and it is likely, therefore, that their causes are not identical.⁶¹

Senescent (Hypertrophic) Arthritis—Although senescent (hypertrophic) arthritis is not generally characterized by as widespread, as deforming or as painfully

progressive lesions of joints as may appear in chronic infectious (atrophic) arthritis, the disability and pain that it produces may at times be most annoying and constitute a considerable handicap. At the onset of symptoms of this disease its victims are generally more than 40 years of age, often more than 50, a time when physicians prefer to apply conservative measures and hesitate to provoke sudden and marked alterations in an accustomed vascular status. Nevertheless, in a number of cases of "hypertrophic arthritis," fever therapy has been employed with reported safety.

Of forty-seven patients with "hypertrophic arthritis" who were treated by Tenney²⁷ with radiotherapy, three (6 per cent) became "symptom free" in an unspecified time, thirty-eight (82 per cent) were "improved," and six (12 per cent) were unimproved. Berris¹⁷ subjected four patients, from 49 to 76 years of age, who had "osteo-arthritis" of from three to twenty years' duration to artificial fever therapy by means of heated cabinets. Each patient was subjected to from seven to twelve sessions of fever at 101 to 102 F for two to three hours. A woman, aged 76, who had suffered with arthritis for twenty-three years, obtained "marked relief from nocturnal pain" and lost her painful sensitivity to changes in weather. The other three patients obtained little or no improvement. Among those treated by King²⁹ were patients with "hypertrophic arthritis," who obtained relief from pain, and increased articular mobility, by means of diathermy hyperpyrexia for two to three hours at 102 to 104 F.

According to Simpson,¹ however, patients with hypertrophic arthritis are poor subjects for this form of therapy, as many of them have cardiovascular and renal insufficiency. Simpson treated twenty-three (?) patients with this type of arthritis, with disappointing results. They did not seem to tolerate the treatments well and any relief obtained was transient.

Summarizing this rather small total experience in the treatment of hypertrophic arthritis by fever therapy we find that, of the total of seventy-four patients enumerated in the various reports to date, only three (4 per cent) became symptom free, thirty-nine (53 per cent) obtained "improvement," and thirty-two (43 per cent) experienced little or no relief.

Gouty Arthritis—A man, aged 44, with chronic gout of three years' duration, was treated by Berris¹⁷ with fever therapy when rest, physical therapy and diet had failed to relieve him and after he had been unable to walk for four months. Six treatments of two hours each at 103 F were given over a period of three weeks. He obtained complete relief and was able to walk without pain after the second treatment. Auclair⁶² is also credited with good results in the treatment of gout. No details are given.

Traumatic Arthritis—Berris¹⁷ also treated two patients with traumatic arthritis. "Complete relief" was obtained in both cases. The first was a case of lumbosacral injury of three months' duration, on account of which the patient had been bedridden for six weeks, without relief from strapping of the back and baths. The second was one of traumatic sacroiliac arthritis associated with constant pain of two years' duration, which was not relieved by a belt. Each patient received five treatments.

Miscellaneous Types of "Arthritis"—Results in cases designated simply as "arthritis," "chronic arthritis" or "mixed arthritis" without any further attempt at differ-

entiation have not been included in the foregoing analyses. Fifteen patients with "chronic infectious and noninfectious arthritis" were treated by Bishop, Horton and Warren²⁴ with an average of less than two sessions of fever in each case. All were "definitely benefited." Twenty patients with "mixed infectious and hypertrophic arthritis" were included among those helped by Simpson.¹ For his patients with "chronic arthritis" who were so treated, Kinsella⁶³ noted only "temporary relief." Coulter,⁶² however, concluded that fever therapy is a valuable adjunct in the treatment of "certain cases of arthritis."

Great success was claimed by Auclair⁶² in his treatment of eighty patients with "rheumatism" of various types—"ankylosing arthritis, various forms of monarthritis, even arthritis of the hip, polyarthritis, infectious monarthritis, gout, sciatica and neuritis, neuralgia, torticollis, lumbago and vertebral arthritis." There were supposedly only seven complete failures.

Neuritis, Sciatica, Myositis, Bursitis—In addition to cases ascribed to Auclair, a few patients with neuritis, myositis and bursitis have been treated by Tenney. Of six patients with neuritis so treated, five became symptom free and one was improved. Of eight patients with myositis, two became symptom free and six were improved. Of four patients with bursitis, two became symptom free and two were improved.

FEVER THERAPY AT THE MAYO CLINIC

Material and Method—In 1932 Sheard, Pratt and Hench⁶⁴ treated a number of patients with arthritis by localized radiotherapy. Instead of subjecting the patient's entire body to the high frequency current, the apparatus was so arranged that only the affected joint came within the electric field. Thus it was hoped to avoid systemic reactions and yet affect perhaps the viability of the presumed invading organisms through a marked local hyperthermia. Results seemed inconclusive and, on the whole, inadequate.

In October 1933 four "Kettering hypertherm cabinets" were installed through the courtesy of Mr. Charles F. Kettering, director of the research laboratories of the General Motors Corporation and Dr. Walter Simpson of Dayton, Ohio. Since then, with the collaboration of Dr. Arthur U. Desjardins, we have treated therewith sixty-six patients who had chronic, nonspecific infectious (atrophic) arthritis and sixteen who had gonorrheal arthritis.

Application of Method Apparatus—The Kettering hypertherm is a large air conditioned cabinet (fig 2) through which heated humidified air is forced by a gentle current induced by a pair of electric blowers. The air is heated by three electric-strip heaters of a total of 1,500 watts and the heat of the cabinet is controlled by a thermostat. It is humidified by a container of water heated by a pair of electrodes and its humidity is controlled at about 35 to 40 per cent by a humidostat. The walls of the cabinet are made of celotex, an adequate insulator, and the cabinet's superstructure fits snugly into position on its couchlike base, preventing any escape of heat. Small sliding doors in the sides of the cabinet give access by which the patient's protective covering of blankets can be rearranged, his skin temperature noted or his rectal temperature taken. The rectal temperature is taken every ten to fifteen minutes, mouth temperatures are not reliable because the patients frequently sip cold water.

Management of Patient—General physical examination of the patient is supplemented by a special detailed examination

of his joints (fig 3) and by certain chemical analyses. He is admitted for treatment in the morning without breakfast and is wheeled on the couch-like base into the cabinet proper, which has previously been heated to about 125 F. The patient having become accustomed to this temperature in a few minutes, the temperature is permitted to rise to about 145 F. The patient's temperature begins to rise and after about thirty to forty-five minutes, he may begin to be restless. Sedatives are then given, but sparingly. In the early stage of a session of fever, 3 grains (0.2 Gm) of sodium amylal or from 1½ to 3 grains (0.1 to 0.2 Gm) of pentobarbital sodium is given. Later codeine rarely

Fig 2—A patient in the Kettering hypertherm

morphine, is sometimes given hypodermically. Others have sought to minimize the "restless period" by giving patients as a routine rather large doses of amylal and morphine, together just before the beginning of the treatment or at the onset of the restlessness, or at both times. It is our belief, however, that the depressing reactions, cyanosis and impending collapses reported by some are frequently due not so much to the patient's reaction to fever as to his reactions to excessive amounts of the sedatives themselves perhaps in conjunction with fever. Using minimal amounts of sedatives at intervals during sessions of fever we have had practically no experience with significant depression of vascular tone or mental irritability.

After about an hour the patient's temperature has generally risen to the desired level that is to be maintained. It can be raised faster, but only with great discomfort to the patient. We consider the optimal rectal temperature for cases of chronic infectious arthritis to be about 104 to 105 F for five hours, and for cases of gonorrheal arthritis to be about 106 to 106.8 F for five hours (figs 1, 4 and 5). When the patient's rectal temperature has reached the desired level, additional blankets are placed over him. The temperature of the cabinet can then be adjusted to maintain the bodily temperature at this level for the required number of hours. The patient's head which is of course outside the cabinet, is cooled by an adjacent electric fan and by frequent sponging with cold water. He is encouraged to sip iced 0.6 per cent saline solution more or less continuously, and from 3 to 4 liters is prescribed to prevent symptoms of chloride depletion. The drink does not taste objectionably salty to the patient who is being treated by fever therapy.

Patients vary considerably in their ability to tolerate fever therapy. A nervous, apprehensive patient may soon request that treatment be stopped and may need considerable jollying and encouragement from the attendant, with recourse to sedatives as necessary. Many patients relax and go to sleep for short periods. Music by means of a radio or phonograph serves to distract and to soothe some, to irritate few. The attendant's personality is a real factor in procuring an adequate and well borne session of fever. Seeing a complacent patient already in the cabinet will sometimes suffice to allay a candidate's apprehension. When the required dose of fever has been given the patient is removed from the cabinet and allowed to rest until his temperature returns to normal (in from sixty to

ninety minutes), after which he takes a warm, and then a cool, shower and is allowed to go home. We have found hospitalization generally unnecessary.

Psychic Reactions to Fever Therapy—Of sixty-six patients with chronic infectious arthritis, only six of the former and none of the latter were unable to tolerate the sessions of fever. Three of these six were unable to complete the initial session and three abandoned treatment after two or three sessions because of discomfort, which in most cases is due to a poor tolerance to heat. In some cases the patient's reaction to heat seems inconsequential but a psychic reaction is noted, a degree of claustrophobia, and patients insist that they "want to get out of the cabinet." One of our patients, who had previously been subjected to febrile reactions from typhoid vaccine given as foreign protein therapy, said he preferred them to cabinet hyperthermia because although he got more relief from the latter, he could enjoy with the former "the luxury of threshing around freely in bed."

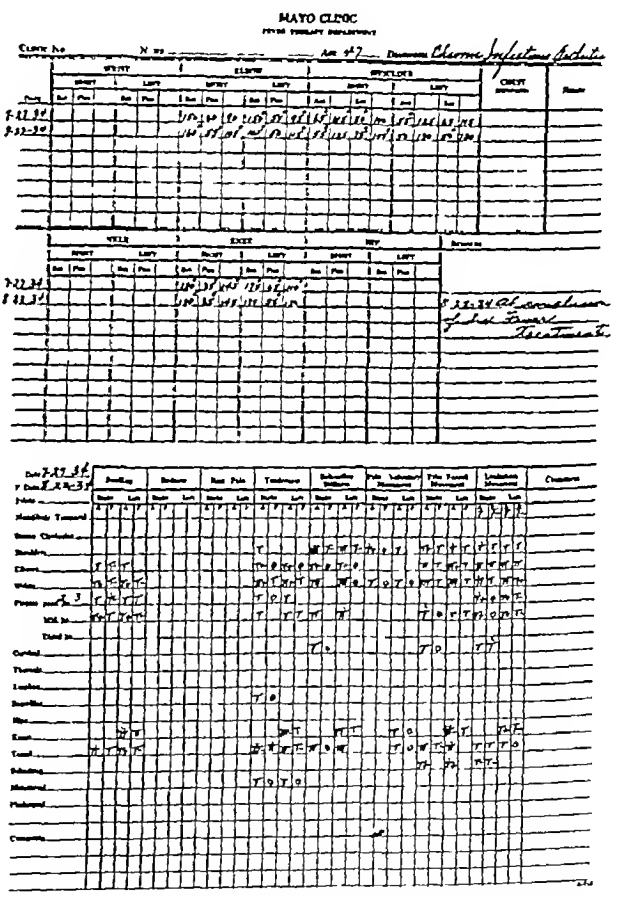

Fig 3—Record card of examination of joints before (A) and after (P) a course of fever therapy upper motion in affected joints lower symptoms and signs referable to affected joints (graded 1 to 4 according to severity)

Physiologic Reactions to Fever Therapy—The pulse rate generally rises to between 130 and 140 beats per minute when the maximal temperature is attained and then falls to between 120 and 130 and remains near this level for the remainder of the period of sustained temperature. If the pulse rate increases to 160 or more, remaining at this level for an hour, treatment is discontinued.

In a series of readings of blood pressure taken before and after 100 treatments 28 per cent showed a drop of

from 20 to 40 mm of mercury in the systolic pressure, and 37 per cent showed a drop of from 20 to 50 mm of mercury in the diastolic pressure. Throughout the treatment a tendency of the pulse pressure to increase gradually was usually apparent. When the systolic pressure drops below 80 mm of mercury and the pulse pressure below 30 mm of mercury treatment should be discontinued at once.

The body weights of 100 patients (eighty-two with arthritis, eighteen with other complaints) were taken

Fig. 4—Readings of temperature and pulse rate during a session of fever for chronic infectious arthritis

before and at the conclusion of their courses of fever therapy. Contrary to popular notion the majority did not lose weight. 79 per cent gained from one-half to 6 pounds (0.2 to 2.7 Kg), 21 per cent lost similar amounts. Loss of weight was due in most instances to vomiting or to inability to take a sufficient quantity (from 3 to 4 liters) of fluids. Nausea complicates treatment in about 20 per cent of cases. Vomiting occurs immediately after the sessions of fever in about 10 per cent of cases, the vomiting often terminates the nausea. In about 3 per cent of cases, protracted anorexia and nausea and frequent vomiting may be encountered for from twenty-four to forty-eight hours, but this condition can be promptly overcome by the intravenous administration of from 500 to 1,000 cc of 10 per cent dextrose and 10 per cent saline solution.

When care is taken and the patient is kept covered with a light cotton blanket, burns on the skin are not observed at body (rectal) temperatures of from 104 to 105 F, but when a rectal temperature of from 106 to 107 F is necessary, as in cases of gonorrheal arthritis, superficial vesicles may develop on the skin if the patient does not remain covered.

Chemical Reactions to Fever Therapy—Determinations of blood lactic acid, made in twenty cases before and after treatment, were within normal limits. Determinations of blood urea in sixty cases, made before and after treatments, were within normal limits. Determinations of blood chlorides in eighty-two cases before and after treatment were within normal limits. (Chlorides by mouth were given to all. The 21 per cent of patients who lost weight are included in the latter group.) Counts of erythrocytes in 100 cases showed no appreciable variation except in two cases, in which there was a drop of about 500,000 cells per cubic millimeter immediately after the first session. In each

of these cases the lowered level attained after the first treatment was maintained for the remainder of the series of treatments. Leukocyte counts were made before and after treatments in eighty cases. There was an increase ranging from 2,000 cells to as much as three times the original count in 69 per cent of the cases. The greatest variation occurred usually in sessions demanding higher temperatures. In the remaining 31 per cent the counts after treatment varied slightly from those before treatment. Determinations of values for hemoglobin were made in 100 cases; there were no appreciable differences before and after treatment.

AUTHORS' RESULTS WITH FEVER THERAPY FOR CHRONIC INFECTIOUS ARTHRITIS

In order to evaluate the results as judiciously and as independent of the patient's subjective reactions as possible, a detailed examination was made, eight characteristics of each affected joint being noted on a special form. At intervals between sessions of fever and at the end of the course a similarly detailed reexamination was made (fig. 3). After a period of from six to fourteen months since the last session of fever, the present status of sixty patients (thirty-six men and twenty-four women) has been determined. Their average age was 36 years (the youngest was 10, the oldest 61). The average duration of arthritis was six and a half years (from one month to seventeen years). The activity of the disease was mild (grade 1) in seven cases, moderately severe (grade 2) in forty-five cases, and severe (grade 3) in eight cases. Thus most of them were ambulatory, but painfully so. The joints involved were few (extension grade 1) in fifteen cases, several (extension grade 2) in thirty-three cases, and many (extension grade 3) in twelve cases.

Immediate Results—At the immediate conclusion of the course of treatment 17 per cent (ten patients) had experienced marked (grade 3) improvement, 46 per cent (twenty-eight patients) had obtained moderate

Fig. 5—Readings of temperature and pulse rate during a session of fever for gonorrheal arthritis

(grade 2) but not striking improvement, 27 per cent (sixteen patients) had obtained but slight (grade 1) relief, and 10 per cent (six patients) had received no relief. None were relieved completely.

According to Pope,⁶⁵ "arthritis may have their pains and stiffness greatly increased at first" with fever therapy. Our patients experienced no aggravation of symptoms.

⁶⁵ Pope, Curran. A Clinical Study of Pyretotherapy (Fever Treatment). Kentucky M. J. 30: 593-605 (Nov.) 1932.

Some have stated that patients who have obtained only moderate relief on the immediate conclusion of their course may with some confidence look for improvement to increase, and that they must not expect to note a full effect for several months. Our evidence does not wholly support this optimism. Of the six patients who were not improved at the end of their session, none were better six months or more later. Of the fifty-four patients who had received variable degrees of improvement, thirty-three later lost some

TABLE 3—*Fever Therapy for Chronic Infectious Arthritis*
Relation of Authors' Results to Duration of Disease

Cases	Duration of Arthritis Years	Improved, per Cent	
		Grade 2	Grade 3
8	1 year or less	37	50
7	1 to 2	43	2.
25	3 to 5	16	8
16	6 to 10	31	6
4	Over 10	0	2.

ground, nine lost only part of what they had gained but twenty-four lost it all. Twelve patients were able to maintain, but noted no augmentation of, improvement. Only nine of the sixty patients noted progressive improvement.

Later Results—At the time of the present inquiry, generally eight to eleven months, and in no case less than six months after completion of treatments, the later results of fever therapy are as follows. Fifty per cent (thirty patients) were apparently no better than before fever therapy, 12 per cent (seven patients) had obtained but slight (grade 1) relief, 20 per cent (twelve patients) had obtained definite (grade 2) though not outstanding improvement, and 18 per cent (eleven patients) had obtained marked (grade 3 to 3+) improvement. While none were entirely symptom free or considered themselves "cured," three of the last eleven patients were "practically well." A man, aged 48, whose moderately active and rather extensive arthritis had been of eighteen months' duration, "can now do most anything" and is "almost normal." Another man, aged 32, who had had arthritis only six months before treatment, has had "no swelling and very little pain or stiffness since." He attends dances frequently and walks freely. A third man, aged 48, considers himself "practically cured." Whereas he "couldn't do anything before the treatments," he "can do almost everything now without pain." Not one of these three patients had had any treatment of any sort since fever therapy over a year ago.

Practically all the patients had experienced exacerbations of variable degrees since fever therapy, even those who had obtained and maintained considerable relief. All but ten of the sixty patients had seen fit to resume treatments of variable types since fever therapy. Two of them had accepted foreign protein treatments by means of typhoid vaccine given intravenously. One was not relieved thereby, the other declared he got more relief from them than from fever therapy.

Relation of Results to Number of Sessions of Fever—Although an attempt was made to give each patient six treatments, the number of treatments varied. A few felt sufficiently improved after three sessions and wished to postpone the rest. Others who noted but little improvement with the earlier sessions persisted and took the full course. Of the sixty patients, thirty-eight had six sessions, one had seven, five had five, four had four, and twelve had three sessions. Although

results doubtless depend in part on giving a reasonable number of sessions, other factors, such as the duration and activity of the disease, are more important. This is evidenced by the fact that of those who had only three sessions, 50 per cent obtained notable (grade 3 to 3+) improvement, whereas none of those who had five sessions and only 13 per cent (five of thirty-eight patients) of those who got six sessions obtained similar relief.

RELATION OF RESULTS TO DURATION, ACTIVITY, AND EXTENSION OF THE ARTHRITIS

As with all other forms of treatment for chronic infectious arthritis, the results of hyperthermia depend to a marked extent on the duration and activity of the disease, and more so on these factors than on whether the patient has four or six fever sessions. Thus the shorter the duration of the arthritis (table 3) and the less its activity (table 4), the more chance there was that the patient would receive an impressive (grade 3) response. There were exceptions, of course, and occasional cases of short duration resisted therapy more stubbornly than some of longer duration.

The number of joints involved was not an apparent factor in the result. Notable results were received as often by those with many affected joints as with few.

Relation of Result to Age of Patient—The age of the patient when treated bore no obvious relationship to the effect of treatment. The group of patients in the decades between the third and sixth, inclusive, shared alike in obtaining both the moderate and marked results.

AUTHORS' RESULTS IN FEVER THERAPY FOR GONORRHEAL ARTHRITIS

Sixteen patients have completed their courses of treatment, thirteen were men, three women. Their average age was 31 years (the youngest was 15 and the oldest 59). Nine were suffering from acute and seven from chronic, gonorrheal arthritis. All had experienced acute arthritis shortly after the onset of an acute urethral or pelvic infection. In ten cases urethral smears made at the clinic were positive for gonococci, in six cases smears were negative here but reliable reports of recently positive smears were given.

4	2		22	18
8	3		37	0
0	4			

us. The average duration of arthritis was thirteen days in acute cases, twelve months in chronic cases.

At the beginning of treatment at the clinic the activity of the arthritis was very severe (grade 4) in five cases, severe or marked (grade 3) in four, moderate (grade 2) in five, and mild in two. Many of the joints were exquisitely tender, markedly swollen and indurated, and they were held completely or almost entirely immobile because of pain. The joints were thus in general much more painfully affected than in the cases of chronic infectious arthritis. The joints involved were generally few (one or two) in about twelve cases, but more numerous in four.

Immediate Results—In our earlier cases from five to seven sessions of fever were given. In later cases, at least of the acute type, from three to four sessions were given, as this number seemed to suffice, as it also did in cases of chronic gonorrheal arthritis. Relief, which is sometimes marked, is often noted after the first session. Of the sixteen patients, on conclusion of their last session of fever, 32 per cent (five) were completely relieved of all signs and symptoms of arthritis (table 5). An additional 37 per cent (six patients) were also completely relieved except for rather insignificant residual stiffness, slight (grade 1) pain of a joint on motion or walking, or slight (grade 1) residual tenderness. Nineteen per cent more (three patients) were markedly relieved (grade 3), and one patient (6 per cent) was moderately relieved. Only one patient (6 per cent) did not obtain benefit, a case of residual chronic gonorrheal arthritis of seven months' duration, with roentgenographic evidence of destructive arthritis and with marked stiffness of the knee but with only a little tenderness and a normal sedimentation rate.

As would be expected, patients with acute arthritis, whose disease is of shorter duration, received somewhat more striking results than those with chronic gonorrheal arthritis, especially those with considerable residual stiffness and destruction of joint tissues. Of those with acute arthritis, 88 per cent were promptly

The status of the patients has changed but little and they have lost none of their improvement. Thus five of them (45 per cent) are still symptom free. Five (45 per cent) are markedly relieved and experience but slight, occasional aching. The one who was unrelieved at the end of the sessions of fever has seen but little improvement (grade 1).

COMMENT

Since our results with the Kettering hypertherm are approximately the same as those obtained with other methods, we agree with Simpson that the use of properly heated cabinets should replace more elaborate methods. Certainly this method is simpler and less expensive than radiotherapy. Simplification of methods to avoid danger and expense and to increase the sphere of hyperthermia's usefulness is highly desirable. We regard as justified the lessening popularity of radiotherapy and "superdiathermy" in favor of heated cabinets. Simplification must not be carried, however, to the point of therapeutic ineffectiveness. There is already a tendency to propose methods of supposed "fever therapy" incapable of providing adequate degrees of fever or of producing much more than the local thermic reactions of ordinary physical therapy.

The results in gonorrheal arthritis are in striking contrast with those in nonspecific infectious arthritis, the figures in the two groups being almost the converse of each other. Of patients with gonorrheal arthritis, well over two thirds are promptly "cured" and practically none go without considerable relief. Of patients with chronic infectious arthritis, about two thirds get little or no relief and only a third are benefited significantly. It is a point for debate how far fever therapy is justified in cases of chronic infectious arthritis if it but infrequently provides more than relief of grade 2. Many less expensive, more available and less strenuous forms of therapy do that much almost as a routine. Based on experiences to date, it seems only fair to tell a candidate for fever therapy who has chronic infectious arthritis that his chances for having the progress of his disease stopped sharply are probably no more than one in five, if that much, and that his chances of receiving little or no benefit are about 50 per cent. If his condition is of long duration or markedly active, or if he has practically ignored older and more orthodox measures, it would seem best to postpone a trial of fever therapy in favor of current therapy of proved usefulness. But it is in just such long-standing and severe cases that one turns in hope to new methods. If the victim has tried other measures faithfully with but little success, if he understands the likelihood of relief, and if he can afford the treatments without undue financial sacrifice, then a trial of hyperthermia seems quite justified. It must be remembered, however, that success is more frequent in cases of short duration and of moderate activity.

Regardless of the apparatus or method used, such therapy will probably never be inexpensive or cheap, for its physiologic effects are potent and it must always be completely under control. The constant presence of trained attendants is required, with a physician either in attendance also or within immediate call.

In gonorrheal arthritis, results are so striking and apparently so superior to those obtained by other methods that one can prescribe fever therapy as the method of choice with considerable assurance. Even though the cost is a matter of consideration, the prompt relief obtained and the avoidance of crippling deformities

TABLE 5—Immediate Results of Fever Therapy for Gonorrheal Arthritis

"cured" or practically so (grade 3+ and grade 4 improvement), being relieved of all significant pain, swelling, tenderness and stiffness. Of the seven patients with chronic gonorrheal arthritis, whose disease was of three, three, six, seven, eight, fourteen and thirty-six months' duration respectively, all were markedly relieved but the one previously mentioned. One was completely relieved and two others were practically relieved. Of these seven patients, three had marked stiffness and destructive arthritis, in each case of a knee, two still had considerable active inflammation, with tenderness, redness and pain. After treatment these symptoms subsided completely, leaving only residual stiffness, as was to be expected. As noted, the one patient with marked residual stiffness but with little if any active disease was not benefited.

These figures apply to the effect of fever therapy on articular infections. In the majority of cases, genital infections were likewise benefited and urethral smears became negative. At times, however, the urethral infections were resistant and extra sessions of fever or other treatment such as the Elliott regimen, had to be used. For details concerning this phase of the problem, reference is made to the paper by Desjardins, Stuhler, and Popp.⁶⁶

Later Results—In eleven of the sixteen cases, from three to fourteen months has elapsed since treatment

⁶⁶ Desjardins, A. U., Stuhler, L. G., and Popp, W. C. Fever Therapy for Gonococcal Infection. *J. A. M. A.* 104: 873 (March 16) 1935.

mity, formerly so often a feature of gonorrheal arthritis, fully justify the expense. In a case of doubtful etiology, in which gonorrhea is suspected but cannot be proved, the patient should be given the benefit of the doubt and subjected to two or three adequate sessions of fever. If a striking result is obtained promptly, the chances are that the cause was indeed the gonococcus. Even in cases of old, chronic gonorrheal arthritis in which the continued presence of viable gonococci may seem remote and secondary invaders are under greater suspicion, a trial of a few sessions of fever is nevertheless in order, and particularly if appreciable degrees of inflammatory activity (tenderness, swelling, and pain on motion) still accompany the residual deformity. The "fire" may finally be stopped by fever therapy, but fever therapy should be looked on as a "fire brigade" and not a "corps of carpenters"; it may extinguish the fires of gonorrhea but will not restore the architecture of a joint. Therefore, when a process is practically burned out except for residual stiffness, fever therapy is probably not indicated.

The difference between results for the two types of arthritis would seem to support the contention that in gonorrheal arthritis, fever therapy exerts a direct (sterilizing) effect but that in nonspecific infectious arthritis its effect is largely if not entirely indirect. If the latter disease is bacterial in origin, its causative germ (streptococcus or otherwise) is obviously not one mortal to the degrees of fever available in clinical hyperthermia. A corollary of this would be that if any of the supposed arthrotropic bacteria put forth as being the primary etiologic agent are found capable of being fairly readily killed *in vitro* at temperatures available in fever therapy, they are probably not the cause of the disease and claims for them should be discarded. Such a conclusion seems only logical. Practically nothing is known about the thermal death time of streptococci, a field for immediate investigation if rational dosage in hyperthermia is to be attempted. Indeed, similar investigations on the thermal death time of all organisms pathogenic to man would seem indicated to determine their susceptibility not to a few minutes of intense heat *in vitro* but to several hours at lesser temperatures *in vivo*. It would be a grim joke if of all such pathogenic organisms only one was susceptible to the direct action of hyperthermia. Fever therapy may yet prove "specific" for more than the gonococcus.

SUMMARY AND CONCLUSIONS

A survey of experiences with fever therapy for various types of arthritis indicates that results have been quite variable. No one method has been proved clearly superior to all others, and a laudable process of simplification of methods is in progress.

Of cases of chronic, nonspecific infectious (atrophic) arthritis, "cures" have been reported in from 0 to 25 per cent, marked relief in from 0 to 7 per cent, moderate relief in from 25 to 50 per cent, and no relief in from 13 to 75 per cent. We have estimated that, of the total number of patients treated, an average of about 10 per cent were reported as becoming symptom free, about 25 per cent reputedly obtained marked relief, about 35 per cent obtained moderate relief, and about 30 per cent obtained no relief.

The results in our cases have not equaled these general averages but have approximated the more modest estimates. Of our sixty patients with chronic infectious arthritis none were completely relieved, 18 per cent were markedly relieved, 12 per cent were moder-

ately relieved, 20 per cent were but slightly benefited and 50 per cent were not relieved. Thus a total of 30 per cent received significant benefit and 70 per cent got little or no relief.

The value of fever therapy for chronic infectious arthritis cannot yet be fully appraised. Further clinical experience is necessary as well as further investigation on the thermal death time of supposedly etiologic bacteria. In the meantime, a trial of fever therapy in selected cases is justified.

Of cases of gonorrheal arthritis, "cures" have been reported in from 50 to 100 per cent, with complete relief occurring in a total average of 92 per cent. Only occasional patients are not markedly benefited.

Our results in sixteen cases of gonorrheal arthritis confirm those of others. About 90 per cent of our patients were essentially cured or markedly relieved. Adequate fever therapy seems to provide a direct sterilizing action on affected joints.

Since one may expect from adequate fever therapy a fairly rapid and essentially complete recovery in the majority of cases of acute gonorrheal arthritis (with out the articular residues that so frequently occur in spite of other measures), and since even in cases of chronic, but still active gonorrheal arthritis considerable benefit can often be obtained, the prompt use of this form of therapy is recommended.

THE DIAGNOSIS AND TREATMENT OF BLACK SPIDER BITE

J. M. FRAWLEY, MD

AND

H. M. GINSBURG, MD

FRESNO, CALIF.

During the last seven years, fifty-two cases of black spider bite have been treated at the Fresno County General Hospital. Most of the cases were admitted during the summer and early fall. The number treated each year was as follows: 1928, 6, 1929, 3, 1930, 3, 1931, 6, 1932, 11, 1933, 12, 1934, 11.

In the average case the patient was an adult male who had been bitten on the penis or scrotum while sitting in an outdoor privy. In some cases, however, there was a history of having been bitten on the foot while putting on a shoe in the morning or on the back or arm after getting into the blankets at night.

The patient when brought to the hospital shortly after being bitten complains of pain and swelling at the site of the injury with pain throughout the body, particularly in the extremities, which become cramped and spastic. This is soon followed by severe pain over the abdomen and rigidity of the abdominal muscles, with nausea and frequently vomiting. Sometimes he complains of burning of the soles of the feet. There is anxiety, headache, ringing in the ears and dizziness. The blood pressure is elevated as much as 35 or 40 mm.

If the injury is slight, only tenderness and cramping of the muscles of the extremities may be noted. The location of the bite determines the rapidity of the abdominal involvement. When the lower extremities or the scrotum are bitten there is more rapid development of abdominal symptoms. The spasm of the muscles in the extremities is always noted previous to the abdominal symptoms.

The physician's attention is particularly drawn to the severe pain in the abdomen. On palpation he finds a

tender abdomen without any point of localization and a rigidity that at times is boardlike and makes him suspicious of a ruptured peptic ulcer

The spider that is responsible for this syndrome is *Latroectus mactans*, the female of which species is known as the Black Widow. It is a large shiny black spider with spherical body and long slender legs. On the ventral side of the abdomen is an hour glass shaped red or yellow spot. The dorsal surface is usually marked by one or more small red dots.

This spider is common in many of the Southern states, where it is found around refuse heaps and in stables and outbuildings but occasionally also in houses both in the country and in cities.

J T Vaughan¹ of Ashland, Va., who has had ten cases, recently writes "These cases are quite a new thing in this part of Virginia. I have two explanations for this. First, the past two years have been very dry and second, the state board of health has installed sanitary privies and a large number of bites have occurred in privies. Apparently the spider, seeking a damp place, stays in privies."

It is generally considered that the bite of the black widow spider is very dangerous if not fatal. In the records of the Fresno County General Hospital, however, there have been no deaths in adults from black spider bite. Bogen,² who compiled records of sixty cases seen at the Los Angeles General Hospital, says that among them there was no mortality. According to him there have been twelve deaths recorded in the literature but no autopsy was performed in any cases so that death might have been due to some other cause.

Kobert³ considers that certain factors might modify the effect of black spider bite. He points out that the poison of the spider may become exhausted after several bites so that for a while little may be left for succeeding bites and also that the poison might enter a blood or lymph vessel with dangerous results or it might remain in the upper layers of the epithelium and do no harm.

There are several other factors that might affect the outcome.

1 It is likely that individual resistance varies greatly, one person being more susceptible than another to the toxin injected by the spider.

2 Since the toxin has a quantitative effect, the size of the individual bitten is an important factor. The amount of poison that would be relatively harmless in an adult might conceivably be fatal in an infant or small child. In children the symptoms are more severe and the outlook is grave. It is a common opinion among physicians practicing in Fresno that fatal cases of black spider bite are not uncommon in small children. In young children there is a rapid development of convulsions, which are extremely difficult to control.

3 While the prognosis in adults is favorable, nevertheless improper treatment may alter the outcome. Alcohol seems to be contraindicated and fatal cases have been reported that may be due to this cause.

A M Cornwell⁴ of Lincolnton, N C., in referring to an article published by him in 1931 says "It is inter-

esting to note that since the above paper was given I have had a death from spider bite. This case is interesting from the fact that the man was partially intoxicated at the time he received his spider bite. He was fishing on the banks of a river and became rather suddenly and seriously ill and his partner discovered one of the black widow spiders up his pants leg, unknown to him. Three days later the man was dead despite all our efforts to save him, having had the classic symptoms of arachnidism."

The successful management of cases of black spider bite depends on two factors: correct diagnosis and proper treatment.

DIAGNOSIS

It is essential that a correct diagnosis be made, otherwise the patient might be subjected to a surgical operation for an acute condition of the abdomen such as ruptured gastric ulcer. If one is on guard it is always possible to differentiate between the abdominal symptoms in spider bite and those of an acute condition of the abdomen. There is generally a history of having been bitten by a black spider and there is no previous ulcer history. The patient is not in shock and the temperature and pulse are normal. The blood examination shows a slight elevation of the white count, with little increase in polymorphonuclear leukocytes.

TREATMENT

In former years many different forms of treatment were employed. For some reason, strychnine was given and the discomfort and pain of the patient was thus unduly prolonged. The most valuable form of treatment was the administration of sedatives, chiefly morphine.

Bogen has advocated the use of blood serum obtained from patients after recovery from spider bite and also the administration of tetanus antitoxin. These measures have not seemed to be necessary in the average case and were not used in this series.

The most rational form of treatment is one based on the clinical picture, which resembles hypertension in the adult and eclampsia in the child, viz., intravenous administration of magnesium sulphate. This treatment was mentioned by Bogen as having been used once in a series of sixty cases described by him in 1932. He says that "the intravenous injection of a 10 per cent solution of magnesium sulphate was given in one instance, with some apparent relief of symptoms." He makes no further comment about it.

The first extensive use of magnesium sulphate in the treatment of spider bite was made in 1933 by De Asis.⁶ He treated successfully four cases of bites by the red spider (*Katipo*), a member of the *Latroectus* family occurring in the Philippines. It was his report which prompted us to apply this treatment to the bite of the black widow spider.

Since the appearance of his paper, the routine treatment for patients admitted with black spider bite at the Fresno County General Hospital has been as follows:

1 The patient is immediately put to bed and iodine is applied to the site of the bite.

2 A soap suds enema is administered, and fluids are given freely by mouth.

3 Morphine sulphate is given hypodermically to control the pain and sodium amytal to insure rest.

6 De Asis Cesario. "Red Back Spider Bite and Magnesium Sulphate Treatment. Clinical Study of Four Cases." Am. J. Trop. Med. 14: 33 (Jan.) 1934.

4 Magnesium sulphate, a 20 cc ampule of 10 per cent solution, is given intravenously, to be repeated as required to overcome the hypertension and the spasticity of the muscles

Results with this form of treatment have been very satisfactory. Last summer we used it in eleven cases. It was never necessary to give more than one dose of magnesium sulphate. The patients were usually free from symptoms within twenty-four hours.

THE EFFECT OF OIL OF PEPPERMINT ON THE EMPTYING TIME OF THE STOMACH

H. I. SAPOZNIK, M.D.

R. A. ARENS, M.D.

JACOB MEYER, M.D.

AND

HEINRICH NECHELES, M.D., PH.D.
CHICAGO

The effect of oil of peppermint on gastric secretion in man and dog is described and balloon tests of gastric motility after oil of peppermint are reported elsewhere.¹ Our previous work showed that oil of peppermint diminished gastric acidity. It was important, therefore, in the analysis of the factors concerned in such a diminution of acidity to investigate the effect of the oil of peppermint on the emptying time of the stomach.

Wallace and Jackson² found that oil of peppermint in the intestine influences gastric secretion by reflex action. Meyer and Gottlieb in their textbook³ state that carminatives increase the muscular activity of the alimentary canal. Muirhead and Gerald⁴ found that small amounts of volatile oils increase the motility of isolated segments of intestine and that larger doses decrease it. In Cushny's textbook⁵ it is stated that volatile oils relax the musculature of the stomach and intestine. Gunn⁶ likewise reported that carminative volatile oils depress the motility of isolated stomach and intestine. Rehfuess and his associates⁷ gave 100 Gm. of "soft creamy wafers with strong peppermint flavor" and noted increased acid secretion but delayed emptying of the stomach. "Soft creamy wafers of strawberry flavor" were given as a control. Samples of gastric contents were taken every fifteen minutes till the stomach was empty. Plant,⁸ using dogs with gastric and intestinal fistulas, reported that spirit of spearmint brought into the intestinal loop increases its tone and contraction. Later Plant and Miller⁹ published experi-

ments on segments and strips of intestine in vitro. Small doses of peppermint increased their motility and tone, larger amounts inhibited it. Stross¹⁰ reported that menthol inhibited motility and depressed and abolished the tonus of isolated pieces of intestine. Arnold¹¹ found a paralyzing action of peppermint on the stomach and a stimulating action on the intestine. Sommerfeld, Kuenzel and Todd¹² observed under the fluoroscope that peppermint increased the amplitude and vigor of the contractions of the stomach.

METHODS

The methods used in this investigation were as follows:

1 *The Balloon Method*—A balloon¹³ and a stomach tube were introduced through the mouth into the stomach of patients (with duodenal ulcers) or normal students who had been without food for twelve hours. In dogs with a gastrostomy, the balloon and stomach tube were introduced through the cannula.¹⁴ The contractions of the resting stomach were recorded by a water manometer in the usual way. After a sufficient control period, oil of peppermint in amounts varying from 2 to 100 cc was injected at one time, at intervals, or by continuous drip (all through the stomach tube). The usual amount given was from 2 to 4 cc, but 100 cc was given only once to a dog. Oil of peppermint, U. S. P., was used.

2 *Duodenal Cannula Method*—A dog with a wide metal cannula in the stomach and another one in the duodenum was kept on a standard diet. He had been without food but with water for from eighteen to twenty-four hours preceding each experiment. Before the test, the stomach and duodenum were emptied by opening the two cannulas. If food was found in the stomach, no test was done. A rubber tube 40 cm long was introduced distally into the duodenum and jejunum through the duodenal cannula and was connected with a funnel that was covered with a wire mesh. The dog was fed 250 Gm. of fresh hamburger with 100 cc of water. After that, the duodenal cannula was opened and the mixed gastric and duodenal secretions were collected. The following day, oil of peppermint was introduced into the stomach immediately after the meal. This was done through a small tube in the gastric cannula. The volume of secretions was measured every ten minutes and the liquid part returned into the intestine through the funnel and rubber tube. The amount of undigested meat was measured and not returned.

3 *Fluoroscopy*—The patients were six young women from Mandel Clinic who had no gastro-intestinal complaints and were all normal, except possibly patient 4, who had gastroptosis without symptoms. They had been without food for nineteen hours. The subjects received a barium sulphate-milk meal and the stomachs were examined before the fluoroscope at ten minute intervals until emptying was complete. The oil of peppermint was added to the barium meal or given in capsules, always in the dose of 2 cc. There was no difference in results noted between the two modes of giving the oil of peppermint. Controls with 2 cc of olive oil instead of oil of peppermint were made.

Aided by the Louis L. Cohn Fund.
Valuable assistance in the technical part of this work was given by Mr. Arthur Pilon.

RESULTS

1 *The Balloon Method*—The results were entirely negative. There was no change in the height, type or frequency of the normal hunger contractions in man or dog when small and probably physiologic doses of oil of peppermint were used. Neither was there a change noted between the duration of the intervals of rest and the activity of the stomach.^{1a} Fifteen tests were performed on thirteen patients with peptic ulcer and five tests were done on a gastrotomized dog. In man, less than 10 cc of oil of peppermint and in the dog less than 4 cc produced no change in motility in eleven trials, and in only one instance did motor depression occur. Large quantities decreased motility in six tests and produced no change in another two.

2 *Duodenal Cannula Method of Kestner*—In three duplicate tests with meat-water alone and meat-water plus oil of peppermint, it was found that while the stomach emptied semidigested food and secretions into the duodenum for three and one-half hours after the feeding of meat and water only, this process was practically terminated in the case of meat and water plus 2 cc of oil of peppermint in two and one-half hours. In the case of the control most of the undigested meat was emptied by the stomach in the first three hours after feeding, and most of the secretion and the digested meat were likewise poured out of the duodenal cannula during the first three hours, while in the same experiment, with the addition of the oil of peppermint, the bulk of the nondigested meat and secretion plus digested meat appeared within the first two hours after feeding.

From table 1 it is apparent that there is a slight diminution in the digestion of meat in the stomach under the influence of oil of peppermint (18 per cent) and less secretion of digestive juices (26 per cent).

3 *Fluoroscopy*—The barium-oil of peppermint mixture was taken easily. There was a slight complaint by a few of the subjects against the strong peppermint flavor. When the oil of peppermint was given in gelatin capsules, the patient noted the taste (or odor) of oil of peppermint after a few minutes.

TABLE 1—Emptying Through Duodenal Cannula

Hours After Feeding	Liquid, Cc		Solid, Cc	
	Control	Peppermint	Control	Peppermint
1	266	273	39	92
2	373	290	65	73
3	248	50	60	12
3½	30	39	0	0
Total	917	682	160	177

In all six subjects there was antiperistalsis during or after the first twenty minutes, which the subjects noticed as nausea. After that peristaltic waves were seen running from the middle of the body of the stomach toward the pylorus, which quickly emptied the stomach. In controls with olive oil (2 cc) no antiperistalsis or nausea was noticed. The emptying time of the stomach varied from 240 to 260 minutes in subjects 1, 2, 3, 5 and 6, and was 310 minutes in subject 4 (gastroparesis without symptoms). Olive oil did not appreciably change the emptying time of the stomach as compared to the control, except in subject 4. Oil of peppermint produced a shortening of the emptying time of from 100 to 145 minutes, expressed as percentage of the controls, from —42 to —49 per cent, with an

average of —46 per cent. It is interesting to note that subject 4, although having a longer emptying time with barium alone (310 minutes, as compared to the other five subjects with from 240 to 260 minutes), had the same reduction of emptying time after barium-oil of peppermint as the other five subjects.

Since some of us have had the experience that peppermint candy or peppermint cordial gives relief after too heavy a meal, this was put to a test in one of the subjects. The ordinary barium meal was given and the emptying time determined (240 minutes). In the next tests, immediately after drinking the barium meal the

TABLE 2—Emptying Time of the Stomach in Six Normal Female Subjects (In Minutes)

Subject	Date of Test, 1933	Barium Control	Barium Plus Olive Oil	Barium + Oil of Peppermint	
				Time	Per Cent Change
1	12/10 to 12/30	240	215	140	—42
2	12/16 to 12/30	250	225	130	—48
3	12/16 to 12/26	260	220	140	—46
4	12/16 to 12/26	310*	230	165	—47
5	12/16 to 12/26	240	210	140	—42
6	12/16 to 12/26	235	220	145	—40
Average 1 to 6		249	220	148	—40

* Omitted from average of barium controls.

subject chewed up a roll of chocolate candy, and on the following day a roll of peppermint candy of the same brand and size, the two of which the patient liked equally well. While after the chocolate candy there was hardly any change (210 minutes), there was a considerable diminution of emptying time after the peppermint candy (150 minutes, i. e., —38 per cent). Similar results were obtained after the patient took 100 cc of 7 per cent alcohol (195 minutes) and 100 cc of 7 per cent alcohol plus 2 cc of oil of peppermint (135 minutes, i. e., —44 per cent).

COMMENT

Peppermint as oil of peppermint, in peppermint candy or in alcohol, undoubtedly has a decided motor action on the stomach as compared to the controls olive oil, chocolate candy and alcohol. It is not easily explainable why this peculiar action was not found in the balloon tests. It is believed that the following may explain it. The hungry stomach has already its own rhythm and the oil of peppermint is not able to augment it. Action on an empty stomach is probably different from that on a full stomach, during hunger and after meals. The tests done on the dog (meat plus oil of peppermint) point to this, but further experimentation will be needed to clear up this point more thoroughly.

The surprising shortening of the emptying time of the stomach with oil of peppermint explains the popular use of oil of peppermint and its use as a constituent of a great number of official and proprietary stomach remedies. The shortening of emptying time after peppermint candy and peppermint alcohol explains the popular habit in this country of offering peppermint candy or peppermint cordial after dinners. In view of our experimental observations, this habit seems to be useful especially after a heavy meal with high fat content, which delays the emptying of the stomach. Oil of peppermint may counteract this delay and make the person feel less full and distended. In a previous paper^{1a} it was reported that oil of peppermint diminishes gastric acidity. This may add to the beneficial action of the drug in heartburn after meals.

Rehfuß's⁷ results are contrary to our observations, but the great amount of candy eaten and the high pep-

permin content of it may explain this. It was found in our tests that oil of peppermint may produce antiperistalsis. Rehfuess did only one such test on one subject.

The shorter emptying of the stomach does not appreciably diminish the digestion of meat (—18 per cent, table 1), although it slightly depresses gastric and duodenal secretions (—26 per cent, table 1). Another observation made in the course of this work by the roentgenologists is worth mentioning. At fluoroscopic examinations of patients, when the observer is waiting for the duodenal bulb to fill, there is often a delay in the emptying of the barium from the stomach into the duodenum by pylorospasm. When a small amount of oil of peppermint is given in gelatin capsules, immediately after solution of the gelatin the barium empties into the duodenum. This study is being continued.

SUMMARY

Dogs fed oil of peppermint with a meat meal showed shortening of the emptying time of the stomach as compared to the control of three and one-half hours, observed with the duodenal cannula method of Kestner.

In six normal young female subjects the addition of 2 cc of oil of peppermint to a barium-milk meal shortened the emptying time of the stomach by 46 per cent (fluoroscopy). Peppermint candy and peppermint flavored alcohol had the same effect in one of these subjects.

ARTIFICIAL FEVER THERAPY IN THE TREATMENT OF CORNEAL ULCER AND ACUTE IRITIS

PRELIMINARY REPORT

E. L. WHITNEY, M.D.

DETROIT

Ophthalmologists for over twenty years have used nonspecific proteins in the treatment of certain eye diseases. The height of fever produced has served at least in part, as a guide to the degree of the reaction. In the use of typhoid vaccine, Howard noted several years ago that fever was essential to a good result. In the last year my associates and I have had an opportunity to use artificial fever alone as a means of therapy in a sufficient number of eye conditions to warrant reporting the results thereby obtained.

Kettering hyperthermia¹ machines were installed more than a year ago in our clinic for experimental work in the treatment of syphilis (principally neurosyphilis), multiple sclerosis, gonorrhea, pelvic peritonitis and arthritis. This apparatus consists of an air conditioned cabinet with which the patient's temperature can be elevated rapidly and maintained at a desired level and carefully controlled for an extended period of time. The entire body, excepting the head, is placed in the cabinet. Mild sedatives are used to keep the patient as comfortable as possible. An electric fan cools the head.

Eight cases presenting varying types of corneal ulcer and six cases of acute iritis are here reported. The results suggest that there is merit in this form of fever therapy, in which the height of the fever and its duration are under such perfect control. Some of the

patients received different types of medication during the fever treatment as well as before, while others had fever therapy only.

ARTIFICIAL FEVER THERAPY IN CORNEAL ULCER

CASE 1—History—H. S., a man, aged 36, a laborer, while passing through a building where scrap wood was being unloaded, Aug. 2, 1934, felt a small particle fly into his right eye. He was sent to the factory hospital, where a foreign body was removed from the cornea and the eye was padded. An ulcer developed which was treated at the factory for thirteen days before he was sent to our outpatient clinic. Another twelve days of treatment followed. This consisted of atropine 1 per cent, silver nitrate 1 per cent to the lids, saline irrigations and 1:5000 corrosive mercuric chloride ointment. Since no improvement occurred the patient was admitted to the Henry Ford Hospital for artificial fever therapy.

Examination—There was a central corneal ulcer 2 mm in diameter. The edges were irregular and moth eaten simulating the dendritic type of ulcer. The iris was well dilated with atropine. The general physical examination was negative.

Course—August 29 the patient was placed in the fever cabinet and a rectal temperature range of from 103.6 to 106.4 F was maintained for five hours. The ulcer began to improve and in four days after this single treatment it was healed.

Subsequent Course—November 2, five weeks after the previous discharge from the hospital, the patient returned with a recurrence of the ulcer. Another fever treatment on November 3 was given with a rectal temperature range of from 105.6 to 106.8 F for five hours. The patient was discharged the next morning and returned on November 8 for his third treatment. The fever range was again from 105.6 to 106.6 F for five hours. Following these treatments there was definite improvement and by November 13 the ulcer was again healed. During the second recurrence no other medication was given except fever therapy. The patient has remained well to the present time.

CASE 2—History—J. L., a man, aged 45, a laborer, was injured Aug. 15, 1934. He noticed an eye irritation and went to the factory first aid station where no foreign body was found. A corneal ulcer developed which was treated at the factory hospital for four days. August 19 he was referred to us for treatment.

Examination—The conjunctiva showed marked chemosis. There was a central corneal ulcer 3 mm in diameter with undermined smooth margins. Hypopyon and iritis were present. The eyeball showed normal tension to finger palpation. The general physical examination including blood, urine and search for focal infection, was negative.

Course—The patient was treated with mild silver protein 10 per cent atropine 1 per cent and hot compresses with saline irrigation. No foreign protein was administered. Fever therapy was instituted the next morning with a rectal temperature range from 104.6 to 106 F for two hours. This seemed to have no effect on the ulcer. Four days later a second fever treatment was given with a rectal temperature from 104.6 to 106 F for four hours. The ulcer did not progress after this but since there was no observable improvement the electric cautery was used. A third fever treatment was given on the sixth day following which the ulcer began to heal and in two weeks was entirely well.

CASE 3—History—A. W., a man, aged 25, a laborer, worked around blast furnaces and said that he often got something in his eyes. Once previously he had a corneal ulcer in the left eye which persisted for three weeks before it healed. He complained of a similar condition.

Examination—There was a small ulcer near the limbus at 6 o'clock and just above this was a larger one with irregular margins and bad appearance. The lids were inflamed. The pupil was regular and not unduly contracted. The iris was not injected. The vision was not reported. No etiologic factor could be found.

Course—The patient was first seen June 30, 1934, when treatment in the outpatient department was instituted. This treat-

ment consisted of atropine 1 per cent, silver nitrate to the lids, metaphen in oil 1 500, saline irrigations, and corrosive mercuric chloride 1 5,000. These medications were used over the period from June 30 to July 23, when the patient reported either daily or every other day for treatment. As progress was unsatisfactory, fever therapy was tried. July 23 the patient was given a treatment with the fever ranging from 105 to 106 F., rectally, for five hours. There was immediate improvement and in eight days the ulcer was healed. August 11 the vision was 6/30. Prior to this attack the patient states that his vision was also 6/30, when an examination elsewhere was made for glasses. Slit lamp examination revealed a rather marked interstitial scarring in the area of the healed ulcer.

CASE 4—History—H L, a man, aged 26, a dentist, was cleaning teeth, when a piece of tartar flew into the right eye. He washed the eye and gave no further consideration to it. Early the next morning he came to us complaining of pain and photophobia.

Examination—There was a small abrasion seen on staining with fluorescein at the center of the cornea. No foreign body was found. The lids were treated with 1 per cent silver nitrate and 1 5,000 corrosive mercuric chloride, and the eye was padded. In three days a definite ulcer formed in spite of daily antiseptic treatment. The ulcer was about 1 mm in diameter and had an infiltrating edge. It was thought best to admit him to the hospital for fever therapy. His general physical examination was essentially negative.

Course—Fever therapy was given, April 30 1934. The rectal temperature range was from 104.4 to 106.6 F for five hours. Two days later the ulcer was healed. During this post-therapy period the patient was using 15 per cent mild silver protein and 1 1,000 metaphen alternating hours during the day.

CASE 5—History—M K, a woman, aged 55 a housewife came to the hospital, Sept 28, 1928, with a small catarrhal ulcer of the left eye. October 5 she appeared with a similar ulcer on the right eye. April 2 1934 another marginal ulcer developed on the right eye. This was treated with 2 per cent silver nitrate and 25 per cent mild silver protein in glycerin, and water was used to flood the entire eyeball while the lids were held apart for from one to two minutes at each treatment. Corrosive mercuric chloride 1 5,000 was also used. The pupil was kept dilated with homatropine. April 19 seventeen days later, the actual cautery was resorted to. May 2, within twenty-four hours three more ulcers had appeared. It was decided to admit the patient to the hospital for fever therapy. She had been for several years under the care of the metabolic division of the hospital and was receiving proper diet and thyroid extract for a recognized hypothyroidism. No focus of infection was found. No protein therapy was given.

Examination—The right eye at the time of the first fever therapy presented three marginal ulcers at 11, 3 and 5 o'clock. The original one at 9 o'clock had practically healed. The general appearance of the cornea was steamy, the epithelium edematous and rough. Tension to finger palpation was normal. The pupil was well dilated with atropine.

Course—The patient was admitted immediately for fever therapy. The fever ranged from 105 to 107 F, rectally. The duration of the treatment was four and a quarter hours. Two days later the ulcers were receding but there was still much infiltration of the corneal margin. There was, however, no longer any pain. After another two days a second treatment was given in which the fever range was from 104.2 to 107.2 F., rectally, for five hours. Two days after this treatment the ulcers were practically healed. May 18 the eye was quite clear and the patient went home.

CASE 6—History—T W, a man aged 65, a laborer had been struck in the left eye with a piece of steel in February 1934. This was removed and a roentgenogram was negative for further foreign body in the eye. He recovered from this without apparent difficulty and was comfortable until ten days before admission, when the eye became sore and inflamed.

Examination—The cornea had a hazy appearance and on staining there were several small points of ulceration. The

iris was swollen and discolored. The vision was not recorded. Roentgen examination was again negative for a foreign body. A general physical examination was negative.

Course—Atropine 1 per cent was instilled and a satisfactory dilatation of the pupil obtained. No other medication was employed. July 5, 1934, fever therapy was given and a rectal temperature range of from 105.4 to 106.2 F for five hours was obtained. The patient did not tolerate this treatment well, as there was a marked fall in blood pressure with an associated hematemesis, suggesting a myocardial failure. July 6, the patient was much improved physically. The corneal epithelium was intact and the cornea presented less infiltration. July 13, the corneal epithelium was still healed but there was scarring. The patient returned August 8, for a check of his glasses. The vision of the affected eye was less than 6/60, because of the interstitial scarring.

CASE 7—History—S J, a boy, aged 15 years, in school, came to the hospital, October 9, with an ulcer of the left eye. It began five days before, when he noticed photophobia, pain, lacrimation, and the feeling of a foreign body in the eye. This eye had been injured previously but the scar had not interfered with vision as a refraction and glasses had given a vision of 6/6 according to his hospital record. There was a history of a swollen knee in 1931, and a tonsillectomy in 1924. His mother had died of tuberculosis.

Examination—There was a breaking down of the old corneal scar in the upper quadrant of the left eye. Infiltration had extended, occupying the upper half of the cornea. The physical examination revealed some tonsillar tags and carious teeth. The chest was clear, and the blood and urine were normal.

Course—The pupil was dilated with atropine and the lids were treated with 1 per cent silver nitrate. The boy was admitted to the hospital the next day, October 10, for fever therapy. The rectal temperature range was from 101.8 to 102.8 F, for five hours. It was impossible to increase the fever at this treatment. October 15 there was improvement, and on October 16 the ulcer was practically healed, one small point still taking a stain. October 18 there was still a small area not healed. The patient was returned for another fever treatment. October 19. Again the temperature could be raised only to from 102 to 103.2 F for five hours. October 25 the cornea was entirely healed. The boy returned November 14 and later had the tonsil tags removed and the carious teeth extracted. His vision one month later was 6/6.

CASE 8—History—R. W, a man, aged 37, a laborer had ulceration of the right cornea which started in January 1934, and of the left eye, which started in April 1934. These ulcers have continued to the present time, January 1935. Before coming to the Henry Ford Hospital Clinic the man had been thoroughly treated. Various standard treatments, including chemical and actual cauterization had been tried. Foci of infection, including tonsillectomy, had been carefully checked. Incidentally, with the tonsillectomy, his asthma disappeared and has not returned.

Oct 27, 1934, Dr R J Coyle of Windsor, Ont, referred the patient to this clinic for artificial fever therapy.

Examination—The lower half of the left cornea presented a destruction of the epithelium with scarring and vascularization and an actively advancing margin. The right eye presented a similar picture, with the right half of the cornea practically gone. The vision was 6/30 in each eye. The lens, iris and fundus of each eye appeared normal. The general physical examination was practically negative. The basal metabolic rate was —14 per cent. The sinuses were clear. The tonsils were small recurrent tags. The urinary tract was normal. Both upper and lower jaws were edentulous. X-ray films showed no retained root fragment. The blood Wassermann reaction was negative and there was no anemia. Skin reactions were negative for allergy. There was no suggestion of tuberculosis.

Treatment—Thirteen fever treatments were given, extending from Oct 27 to Dec. 13, 1934. Some of these were given at intervals of from three to four days, while others were a week or so apart. The temperature range for each treatment was from 104 to 106 F for a period of five hours. After these treatments no very definite change could be seen in the eyes, and fever therapy was finally abandoned.

ARTIFICIAL FEVER THERAPY IN ACUTE IRITIS

CASE 1—History—R J, a man, aged 46, a salesman, for the past twelve years had had eight attacks of iritis in the left eye and one in the right. Some of these were very severe, causing great congestion and even hemorrhages. He stated that leeches had been employed. A careful search for foci of infection was made in past attacks. This attack in the left eye had been in progress one week.

Examination—The iris was well dilated with atropine. Old points of adhesions were seen on the anterior surface of the lens. There were no hemorrhages. The fundus was normal. Tension to finger palpation was normal. The right eye was not involved. The vision with glasses was 20/50 right and 20/200 left. The general physical examination, including a blood Wassermann test, was negative. It was decided to try fever therapy.

Course—Fever therapy May 7 1934, gave a rectal temperature of from 105 to 107 F for five hours. The eye was examined two days later and there were still some precipitates present, but there was less pericorneal injection and the iris was less swollen. May 14 a second fever treatment was given. The temperature range was from 104 to 106 F for five hours. The eye was examined four days later and there was quite definite improvement. No further treatments were necessary. One month later the man appeared with an acute cold and four months later with another, but each time there was no evidence of iritis.

CASE 2—History—P M, a man aged 34, a laborer, was referred to us May 2, 1932, for treatment of the right eye. He stated that sand was blown into it at the factory. There was pain, photophobia, and the feeling of a foreign body in the eye. The duration was ten days. An acute iritis was found. Physical examination revealed chronic tonsillitis, gingivitis and chronic prostatitis. There was a negative Wassermann reaction. While he was in the hospital atropine and typhoid vaccine were used. The iritis cleared in ten days. The prostatitis was later treated in the outpatient department. Jan 2 1935 the patient was returned to us again with a similar complaint and condition of the right eye.

Examination—The cornea was infiltrated and dull, there was deep pericorneal injection and tenderness. The iris was swollen and not dilated.

Course—On this admission the iris was dilated with atropine, and fever therapy was given at once. The rectal temperature range was from 105.4 to 107.6 F for five hours. The following day the iris was much less edematous, the cornea was much clearer, and the pain and tenderness had largely subsided. Two days later the inflammation had practically subsided and the patient was discharged from the hospital to return to work.

CASE 3—History—A H, a girl, aged 14, in school, seen March 7 1934, complained of pain and redness in the left eye. This had been present for some time and had been treated elsewhere. She had been a patient in 1933, when glasses were fitted. At that time there was no history of previous difficulty except that of blurred vision, which the glasses corrected.

Examination—The pupil of the left eye was well dilated and there were no adhesions. Pericorneal injection was present and there were precipitates in the anterior chamber. Further examination revealed tonsil and adenoid tags as the only possible focus. A tuberculin test was not made at this time. The Wassermann reaction was negative.

Course—The patient was given an ampule of calcium gluconate intravenously and atropine instillation. The eye looked better and there was no pain on the succeeding day. By March 16, nine days later under calcium gluconate therapy, there had been slow improvement, but precipitates still persisted. Artificial fever therapy was then instituted. March 17 a treatment was given with a temperature range of from 104.6 to 105.6 F rectally for five hours. There was further evidence of improvement noted on March 19. A second treatment was given on March 22. The rectal temperature was raised to from 104.6 to 106 F for five hours. By March 25 the iritis had cleared quite well except for a few remaining precipitates. At this time the left disk was found to be quite hyperemic and the vision reduced to 6/30. Visual fields were not altered. The

right eye was normal. A neurologic consultation was negative. The patient had no reaction to 0.1 mg of old tuberculin intracutaneously. By June 4 the optic neuritis had improved and the vision was 6/75 without glass correction. The patient returned recently and there is no residual evidence of either optic neuritis or iritis. The vision in each eye is 6/75.

CASE 4—History—W B, a man aged 53, a laborer, complained of pain, inflammation and difficult vision in the right eye for about two months. He stated that no injury to the eye had occurred. There had been no previous attacks.

Examination—There was marked ciliary injection, the iris was muddy looking and there was marked infiltration of the cornea. The tension was normal to finger palpation and the pupil was not dilated. The general examination revealed malnutrition and possible arthritis of the knee and shoulder joints. There was no focus found in the tonsils, sinuses, teeth or prostate. The blood Wassermann reaction was negative.

Course—April 9 1934 fever therapy was given and a rectal temperature of from 105.2 to 106.4 F for five hours was obtained. The next day the eye looked improved. Atropine 1 per cent was instilled. April 13 there was further improvement. The patient did not return until two weeks later, when the condition was worse again. Another fever treatment was given on April 27 and a rectal temperature range of from 105 to 107 F was obtained. The patient never returned following this second treatment. A recall letter has failed to locate him.

CASE 5—History—J D D, a man, aged 47, an engineer seen in December 1927, had an acute attack of iritis in the left eye. Examination showed an infection in the tonsils. These were removed and along with atropine and salicylates the iritis cleared in three weeks. He returned in August 1930 with a recurrence. A search for a focus was negative. This time typhoid vaccine was used and the eye improved in one week. In October 1933 there was a third recurrence. This time calcium gluconate intravenously was used and the eye cleared in four days. The fourth attack came on Feb 17, 1934 and the right eye became involved, February 20. Under atropine and calcium gluconate the eyes subsided rapidly. A fever treatment was subsequently given in an effort to see whether it might be of value in avoiding a recurrence. February 27 a rectal fever was obtained ranging from 105.4 to 106.4 F. A second treatment was proposed but not carried out. The comment from the patient, contained in a letter dated April 10 1934 was to the effect that this treatment impressed him as the best of any form of treatment given him.

CASE 6—History—E J M, a man aged 34, a laborer, seen May 26, 1934 stated that oil had been splashed in the right eye one week before. The eye was painful, and marked photophobia and lacrimation were complained of. There was a history of a gonorrheal infection eighteen years before. In 1926 he was admitted to the hospital with a diagnosis of chronic arthritis, tonsillitis and prostatitis. The prostatitis was treated and the patient disappeared.

Examination—The right eye presented a marked injection with a steamy cornea and a tonometer reading of 90. It was felt that this was a secondary glaucoma superimposed on an acute iridocyclitis. The general examination disclosed chronic tonsillitis, a normal prostate and a negative Wassermann reaction. Dental roentgenograms were also negative.

Course—The first fever treatment was given immediately. A rectal temperature of from 104 to 105.8 F was maintained for four hours. There was definite improvement the following day. The second fever therapy three days later, May 29, gave a rectal temperature of from 105 to 106 F for five hours. The next day there was still marked improvement. By June 9 fourteen days after the first treatment practically all injection had gone and the tension was 20. By June 12 the fundus could be readily seen and gross objects noted. June 21 the vision was 6/30 without glasses. A tonsillectomy was done, June 27. No subsequent report is available.

SUMMARY

1 *Corneal Ulcers*—Eight cases of corneal ulcer were treated and are reported in an attempt to evaluate their response to artificial fever therapy. The results

may have been influenced by the necessity of continuing other forms of therapy at the same time. Nonspecific protein therapy was purposely omitted.

Four of these cases presented a history of trauma, three were considered catarrhal and one Mooren's ulcer. A general physical examination was done on each patient in an attempt to check any etiologic or associated factors.

Patient 1 was treated twenty-five days without healing, and after one fever treatment was well in four days. Five weeks later a recurrence was twice treated by fever and promptly healed, without any local medication.

Case 2 seemed to heal more rapidly after the electric cautery was applied.

Case 3 was treated medically twenty-three days before fever therapy and healed in eight days after one treatment.

Case 4 seemed to make more progress after one fever treatment than before with medical therapy alone.

Case 5, with catarrhal ulcers, healed with fever therapy in eight days, after having had medical treatment alone for one month.

Case 6, probably a catarrhal ulcer, responded quickly after one fever treatment.

Case 7 seemed to improve after each fever treatment.

Case 8, Mooren's ulcer, after thirteen fever treatments made no response.

2 Acute Iritis—Six cases of acute iritis were treated. A general physical examination was made in each case to determine any etiologic factors. Little help was obtained from these surveys. Atropine was used in all cases. No nonspecific proteins or salicylates were given. Calcium gluconate was used in two cases before fever therapy was instituted.

Cases 1 and 5 are of the chronic recurring type. Fever therapy was given to determine its effect on recurrences. Time is required to decide the final result.

Patient 2 returned after two and one-half years with a second attack. This subsided promptly after one fever treatment.

Case 3 improved as to the iritis, but an optic neuritis did not respond until after tonsil and adenoid tags were removed.

Patient 4 was inadequately treated, owing to lack of cooperation.

Case 6 was most striking. A severe iridocyclitis, with secondary glaucoma, responded quickly and favorably to fever therapy.

CONCLUSION

Prompt healing of some corneal ulcers after fever therapy is a striking fact. Local treatment is quite adequate in many cases, but fever treatment has hastened healing when local measures have seemed to be making little progress. This is particularly true in cases in which systemic stimulation is indicated.

The production of artificial fever in acute iritis is of definite value. Recovery is hastened. Further observation is necessary to determine the effect it has in preventing recurrences.

How to Become Fat or Thin—Eating about 500 calories a day more than you spend will result in a gain of about a pound a week. Eating about 500 calories a day less than you spend will reduce your weight about a pound a week.—Sherman H. C. Food and Health New York, Macmillan Company, 1934.

TREATMENT OF GONORRHEA IN THE FEMALE

BY MEANS OF SYSTEMIC AND ADDITIONAL PELVIC HEATING

WILLIAM BIERMAN, M.D.
AND

EDWARD A. HOROWITZ, M.D.
NEW YORK

We have found that the combination of systemic temperature elevation with simultaneous additional pelvic heating constitutes a method of treatment rapidly effectual in gonorrhea in the female. Our work is based on the fact that the gonococcus can be killed by temperatures that are not injurious to body tissues. The important considerations are the temperatures produced in the tissues in which the organism exists and the duration of the temperature elevation.

We have treated twenty-three female patients with gonorrhea whose subsequent course we have been able to follow closely. Ten of these patients previously had local chemical treatment, which had failed to cause the disappearance of gonococci. Eighteen of our twenty-three cases were complicated by salpingitis, six in the subacute and twelve in the chronic stage. In all these eighteen salpingitis cases, gonococci were found in smears of the secretions obtained from the cervix. In nine, gonococci were also obtained from the urethra. Of the five other patients, two suffered from gonorrheal arthritis (gonococci were found in the cervical and urethral secretions of both), one patient had an acute cervicitis only, one an acute urethritis with an accompanying Bartholin's abscess, another suffered from a combination of gonorrheal cervicitis, urethritis and proctitis.

These patients received an average of a little less than three treatments each. This caused the complete disappearance of gonococci in nineteen of the twenty-three cases. In two of the remaining four cases the gonococci disappeared from the cervix (after two treatments each) but persisted in the urethra, from which they disappeared after the coagulation of Skene's ducts. One patient with cervicitis, to whom a single treatment was administered, received a few subsequent applications of silver nitrate, which were sufficient to cause the disappearance of some persisting organisms. In one case, complicated by the presence of a severe gonorrheal proctitis, the organisms disappeared from the cervix and urethra but persisted in the rectum. In the two months subsequent to the treatment, nine smears revealed no gonococci in the secretion from the urethra and the cervix. However, the continued discharge from the rectum of pus containing numerous gonococci indicated the persistence of the proctitis. Immediately after a menstrual period two months subsequent to the treatments, the patient observed a return of the vaginal discharge. On examination, a purulent secretion was seen issuing from the urethra. It contained numerous pus cells loaded with gonococci. This appeared to be a reinfection of the urethra from the rectal discharge. The cervix remained clean. This case well illustrates the value of combined local and systemic temperature elevation. Evidently the organisms existed at a point in the alimentary tract beyond the region of high local temperature produced by the technic we employ.

From the Departments of Physical Therapy and Gynecology, Beth Israel Hospital.

In all our other cases, frequently repeated examinations have failed to reveal the recurrence of gonococci.

With the disappearance of the gonococci, the abnormal discharges usually cease. From the urethra no discharge can be expressed, or only a very scant milky discharge, which microscopically contains many epithelial cells, a few leukocytes and Doderlein bacilli. The cervical secretion becomes clear, mucoid, and in most instances scant. In a few multiparous patients with lacerated eroded cervixes a moderate discharge persisted. Cervical smears continued to contain a moderate number of leukocytes, not clumped mucus and sometimes a number of bacteria, especially gram-negative bacilli and gram-positive cocci. These gram-negative bacilli were often seen in large numbers immediately after the disappearance of the gonococci. In some cases the abnormal secretions disappeared while gonococci were still present. In several cases enlargement of a Bartholin gland disappeared after the treatment, and secretion could no longer be expressed from its duct.

During the first treatment in cases presenting salpingitis or arthritis there is usually a cessation of pain which may or may not subsequently recur. In most cases, pain is absent after the second treatment. In five salpingitis cases there was a later recurrence of pain without fever, although no gonococci could be found. The pain disappeared in two of these cases after a week of rest in bed. In two other cases the pain was relieved by ordinary pelvic diathermy treatments. In one case our combined treatment was repeated five weeks later with relief of pain.

Pelvic examination within a few days after treatment usually reveals a marked diminution of pelvic tenderness but little change in the size of the adnexal masses. From seven to ten days after treatment there is usually an increased mobility of the uterus and some shrinkage of the inflammatory masses. About two weeks after treatment the adnexal masses become very much smaller. Five of our eighteen cases of salpingitis still presented some enlargement of the adnexa when examined several months after treatment. Two of these had been in the subacute stage when treated and the other three in the chronic stage. These masses were very much smaller than they had been originally. In only one of these five cases was the residual mass as large as a tangerine orange. This patient had had repeated attacks for eight years. She entered the hospital with a mass in the right lower part of the abdomen extending to an inch above the anterosuperior iliac spine. There was a smaller mass on the left side. She received a total of eight treatments, following which the adnexal masses subsided but did not disappear. Her only complaint now is polymenorrhea, which has persisted since a year before the treatment.

A fairly typical case history is that of F. L., aged 23, who was admitted to the gynecologic service at the Beth Israel Hospital, Nov. 9, 1933, complaining of abdominal pain and irregular vaginal bleeding. The menstrual periods occurred at intervals of from one to three months and were of five days' duration, with a normal flow and no pain. She had had two induced abortions. For the past six months there had been a greenish vaginal discharge. Two weeks before admission, at the time menstruation was expected, she began to have vaginal spotting, followed by pain in the lower part of the abdomen. Six days before admission the pain became more severe and clots were passed from the vagina. The temperature on admission was 100.6 F.

Thereafter there was a daily elevation a little over 100 F., until the first treatment was administered on her sixth day at the hospital, after which her temperature was normal. Examination on admission revealed tenderness in the lower part of the abdomen and marked tenderness on the right side of the pelvis. There was moderate vaginal bleeding. The leukocyte count was 14,000, with 74 per cent polymorphonuclears. Hemoglobin was 59 per cent and red blood cells numbered 3,300,000. The red blood cell sedimentation (Weiss modification of Fahraeus test) was 75 mm in forty-five minutes (over 10 mm is abnormal). Cervical and urethral smears contained intracellular gram-negative diplococci. Examination on November 10 elicited pain on moving the uterus. There was a tender mass on the right side, somewhat fixed, also a smaller mass on the left. The diagnosis of gonorrheal salpingitis was made. The vaginal bleeding ceased, but when the first fever treatment was administered, November 14, there was still considerable pain in the lower part of the abdomen. During the first treatment the pain disappeared and did not recur during the patient's stay in the hospital. However, gonococci were still recovered from the cervical secretion, so that a second treatment was administered two days later. Smears from urethra and cervix thereafter did not reveal any gonococci on repeated examination (November 18, 19, 20, 21, 22, 23, 27 and 29, December 1, 4 and 11, January 15 and 28, February 5, and March 5). The red blood cell sedimentation on November 15 was 56 mm, on the 19th 22 mm, on the 20th 16 mm. On January 15 it was within the normal range, 6 mm. Examination on November 18 elicited no pain. There was a definite thickening in the region of both adnexa and also in the culdesac of Douglas. There was moderate mobility of the uterus. The rectovaginal septum was indurated, especially toward the left. November 23 a discharge note described the uterus, anterior, as freely movable, the right adnexa were not palpable, the left were somewhat enlarged and tender, there was a thickening in the region of both sacro-uterine ligaments. When seen in the follow-up clinic, December 4, the patient felt perfectly well. The adnexa were palpable and slightly tender. Jan. 15, 1934, she was feeling well. She had just had a normal painless menstruation. No discharge was present. The adnexa were slightly thickened, the right twice the normal size and somewhat fixed. February 5 there was no pain or discharge, the left adnexa were a little larger than normal, fixed and not tender. March 5 the patient felt very well, but the left adnexa were still a little enlarged.

We have observed in other subacute salpingitis cases, as in the one just described that the subsidence of the inflammatory process after treatment is paralleled by a return toward normal of the rate of red blood cell sedimentation. This was noted by us previously in cases of pelvic inflammation treated by radiotherapy.¹

In cases complicated by salpingitis, our best results have been obtained in the subacute and chronic stages. We prefer to wait for a period of about two weeks after the onset of an acute tubal infection.

The technic we now employ consists in the use of pelvic diathermy while the patient lies within a hood containing carbon filament lamps. By means of diathermy alone it is possible to maintain a temperature

¹ Bierman, William and Horowitz, E. A. General Hyperthermia with Heat Localization by Radiotherapy in the Treatment of Pelvic Inflammatory Disease. *New York State J. Med.* 33: 218-223 (Feb. 15) 1933.

in the vagina of 108 F, which is 85 degrees above the normal. The temperatures in the bladder and rectum are usually elevated to within 15 degrees of the vaginal temperature.² The temperature of the tissue of the cervix, as indicated by a thermocouple needle inserted into it, becomes elevated to within about 15 degrees F of the temperature registered by the vaginal electrode thermometer. The additional use of a cabinet surrounding the body, containing photothermal lamps, causes a rapid elevation of general body temperature, because of the prevention of heat loss from the body and the introduction of further heat energy into it.³ This combined use of heat by diathermy and phototherapy is usually sufficient to cause an elevation of the systemic temperature (as indicated by the temperature of the mouth) to from 105 to 106 F, within the period of about one and one-half hours. The vaginal temperature, as indicated by a thermometer in the vaginal electrode, is then easily raised to 111 or 112 F. These temperatures are maintained for a period varying from three to four hours.

The sensations of the patient undergoing treatment are those usually experienced during hyperpyrexia induced by high frequency currents. There is sometimes a sensation of pelvic warmth, but the patient is usually conscious only of a diffuse heating of the entire body. During the period of transition from normal temperature to 104 F there is usually restlessness and general discomfort for which morphine or one of the barbiturates may be given. There is no pain at any time.

We have accepted for treatment only patients in good general condition, without cardiovascular or pulmonary disease or marked obesity. Treatments are not administered four days before the expected time of menstruation, during the period, or for three days afterward. Pregnant patients with gonorrhea have not been treated.

The only ill effects experienced by our patients have been the weakness and malaise complained of by some patients for a few days after treatment, herpes labialis, and in a few cases areas of coagulation of the vaginal mucosa. No serious ill effects were experienced in any case, nor was there aggravation of the pelvic inflammatory condition in any of our cases of salpingitis.

The idea of combined systemic and still higher local temperature elevation occurred to us five years ago.⁴ We described a technic for accomplishing this by means of short waves⁵ and reported the clinical results obtained by the use of this technic.¹ As we used the short wave radiation only for the purpose of temperature elevation and not for its maintenance, the differentially increased pelvic heating disappeared during the period in which the systemic temperature elevation was maintained only by means of the cabinet containing photothermal lamps. We subsequently attempted to maintain an increased temperature within the pelvis by means of diathermy applied to the hyperthermic patient after she had been transferred from the short wave machine (radiotherm), applying diathermy by means of a vaginal electrode and a suprapubic one. With this technic the current that it was necessary to employ

sometimes caused painful induration in the fatty tissues of the suprapubic region. We therefore abandoned this technic, until we determined to increase the area of our dispersive electrode. The employment of two large plates, one on the abdomen and the other under the back, as dispersive electrodes, was not always sufficient to prevent injury to the subcutaneous fat, even though we used a flannel pad soaked in a 10 per cent salt solution under the plates. We found it desirable to add two other plates about 3 inches wide and 5 inches long, applied to the outer aspect of each thigh.⁶ These four dispersive plates were connected together to one terminal of the diathermy machine while the vaginal electrode was connected to the other terminal. With these large areas of application of the surface electrodes, overheating of the subcutaneous fat does not occur.

We ordinarily employ from 1,800 to 3,000 milliamperes of current as indicated by the hot wire meter. The current strength is varied to produce desired changes in the vaginal temperature. We found that a vaginal temperature between 111 and 112 F (as indicated by the thermometer in the vaginal electrode) may ordinarily be maintained for a period of three and a half hours without causing tissue damage. A special vaginal electrode with rounded blunt edges minimizes the danger of mucosal burns.

The heat tolerance of human tissue has been determined by several workers. Kolmer and Liebesny⁷ found that the diathermic coagulation of the scrotum of dogs did not occur below 113 F. Kyaw⁸ demonstrated by the application of diathermy that 112 F was the highest temperature that was tolerated by the human urethra without necrosis. Lavake⁹ found that 113 F developed in the cervix by means of diathermy was the highest temperature that did not cause a slough. Roblee and Royston¹⁰ state that the threshold of living cell tolerance to heat is slightly over 112 F.

We observed that coagulation of the vaginal mucous membrane was produced in some cases by temperatures over 113 F or sometimes by 112 F, maintained for a period longer than three and one-half hours. In these cases healing occurred within from four to six weeks, leaving areas that appeared normal.

To permit a prolongation of pelvic heating and to reach tissues beyond the posterior fornix, we insert a large electrode into the rectum and maintain it there for a period of from one and one-half to one and three-fourths hours prior to the insertion of the vaginal electrode. If the rectal diathermy is maintained for a period longer than one and three-fourths hours, some patients will develop pain in the rectum which may persist for several days.

A method that may be used to prolong the period of pelvic heating and yet avoid damage to the vaginal mucous membrane is to circulate cool water through the vaginal electrode. The temperature of the electrode may be lowered a few degrees without appreciably lowering the temperatures produced in the cervix and other pelvic tissues.

Our present technic is a satisfactory one but, undoubtedly, further improvements will be made in

the course of time. Illustrative of the improvements in our technic is the fact that our first eleven cases in this series required an average of 33 treatments, while an average of 22 treatments sufficed to accomplish our objective, the disappearance of the gonococci, in the last eleven cases. Four cases required only one treatment. The average of the number of treatments required was considerably raised by the one case described with the huge pelvic mass extending to well above the anterior superior spine of the ilium.

The degree of systemic temperature elevation may be varied by modifying the intensity of the photothermal energy and of the diathermy current applied to the body. It is dangerous to permit the systemic temperature to go above 107 F. We determined the systemic temperature by means of a clinical thermometer inserted under the tongue. In heating of the entire body, we have found that the mouth temperature averages 0.7 F lower than the rectal temperature. At times the mouth temperature may be higher and at times more than 2 degrees lower than the rectal temperature.¹¹ In addition to the frequent systemic and local temperature observations, it is necessary to note constantly the general condition of the patient (color, character and frequency of the pulse rate and respiratory rate and the like).

There are various strains of gonococci. This may account for the different reports of the thermal death period of these organisms. Thus Corbus and O'Connor¹² stated that it was possible to destroy gonococci instantly at 45 C (113 F), while Schofield¹³ found that at this temperature thirty minutes was necessary. Boerner and Santos¹⁴ stated that the time required was thirty-seven minutes, and Van Putte¹⁵ that it was more than six hours. Carpenter and Boak¹⁶ showed that there were great differences in the thermal death times of different cultures of gonococci. From their in vitro studies of the organisms isolated from a given individual they could definitely predict the temperature and time required to kill these organisms in vivo. At the upper limit of systemic temperature elevation to which the human subject could be exposed with reasonable safety (41.5 C) the time required to kill all the organisms varied with different strains of gonococci from six to twenty-six hours.¹⁷ To maintain a systemic temperature of 41.5 C for more than six hours is trying for the patient and difficult for the doctor. The bacteriologic complexities of the investigation of the thermal death times of organisms isolated from each clinical case, particularly in view of the fact that one patient may harbor several different strains, makes it impracticable to use this procedure for ordinary purposes.

The time required to kill the gonococcus diminishes greatly at higher temperatures. Boerner and Santos¹⁴ found that at 44 C gonococci were destroyed in half

the time required at 42 C and in less than one-third the time required at 41 C. As the organisms are localized in a definite part of the body in pelvic infections, the logical therapeutic procedure would create a temperature elevation within the safe upper limits of tissue tolerance in the region harboring the organisms. We have found this upper limit to be 44.5 C (112 F) and believe that the combination of systemic temperature elevation with coincidentally higher local pelvic temperatures accomplishes this with maximal effectiveness.

Any method that produces a definite rise in pelvic temperatures is of value in the treatment of gonorrhea. The best procedure for pelvic heating, heretofore, has been diathermy. While diathermy does produce substantial temperature elevations in the pelvis, the upper limit of maintained temperature is usually not beyond 108 F, and the temperature gradient from this region to other parts of the body is so sharp that the average elevation of mouth temperature is no more than 0.7 F. It is possible by means of diathermy to produce a vaginal temperature elevation to 110 F or higher, but this temperature level cannot be sustained for long periods by diathermy alone.

In our experience the temperature elevations produced by the Elliott method do not equal those produced by diathermy, yet good results have been obtained with the Elliott treatment by Holden and Gurnee¹⁸ and by others. The Elliott treatment uses a soft rubber vaginal applicator distended by the circulation within it of hot water, at a temperature of from 120 to 130 F.

With all thermal procedures it is possible that the effects other than the direct bactericidal one may be responsible for a definite improvement. These effects include the induction of an active hyperemia with the increase of blood and lymph flow, the increase in the number of leukocytes and the acceleration of their phagocytic activity.¹¹ These factors, as well as the attenuating influence on the gonococci of a temperature elevation insufficient to exert a direct lethal effect, may also account for the fact that such organisms as remain succumb more readily to the action of the ordinarily employed germicidal solutions.

The local measures that have been applied for the heat treatment of female gonorrhea include not only the Elliott hot water bag and pelvic diathermy, which have been mentioned, but also the use of hot vaginal douches or irrigations and the application of various heated instruments. Guttman¹⁹ treated the urethra and the cervix by means of sounds electrically heated to 130 F. Diathermy was applied within the urethra and the cervix by Cumberbatch and Robinson,²⁰ who used metal rods as active electrodes. A temperature of 114 F was developed within tissues in contact with the active electrodes and maintained for ten minutes. Treatments were repeated twice a week. Corbus and O'Connor¹² used a similar technic except that the treatments were of thirty minutes' duration and were administered once in from seven to ten days. Duncan,⁹ using a small Chapman vaginal electrode equipped with a thermometer, applied vaginal temperatures up to 110 F for from thirty to forty-five minutes each day. This requires a powerful diathermy machine using a

continuously increasing current strength (up to 3,500 milliamperes) Two European workers have reported cures of female gonorrhea following a single prolonged vaginal diathermy treatment Kyaw²¹ applied vaginal diathermy at least three or four hours continuously, sometimes giving a total of nine hours of treatment in a single day Temperatures between 106 and 109.4 F were maintained in the vagina Van Putte²² administered vaginal diathermy treatments of five hours' duration, developing a temperature of 104 F in the vagina

Chronic gonorrhea in the female has been treated by means of systemic fever produced in various ways Patients have been inoculated with the plasmodium of malaria or injected with one of a number of pyrogenic substances In addition, therapeutic fever has been produced by physical measures, such as hot baths, radiant heat and high frequency currents With malaria, a series of from nine to twelve fever bouts has usually been employed The malaria treatment has been reported by different workers to cure between 66 and 83 per cent of female patients with chronic gonorrhea²³

In those cases in which gonococci were still present at the end of malaria treatment, a short period of local (chemical) treatment usually resulted in cure²⁴ Most of these cases had previously failed to respond to local treatment Warren and Wilson,²⁵ who induced therapeutic fever by means of high frequency currents, cured three of six cases of chronic female gonorrhea by a single fever treatment of five hours at 106.5 F The three cases in which gonococci persisted became negative after a few local treatments

SUMMARY

A method for intense prolonged heating of the female pelvic organs has been found rapidly effectual in the treatment of gonorrheal infections A systemic temperature elevation of from 105 to 106 F is produced by means of pelvic diathermy and phototherapy during a period of from one and one-half to one and three-fourths hours With the use of a special vaginal electrode equipped with a thermometer, the vaginal temperature is maintained between 111 and 112 F for three and one-half hours A special arrangement of four dispersive electrodes is necessary The treatment is painless but there is discomfort from the systemic fever Constant watchfulness throughout treatment is imperative An average of less than three treatments caused the complete disappearance of gonococci in nineteen of twenty-three patients treated In two of the remaining cases the cervix was freed from gonococci after two treatments but not the urethra In these two cases, coagulation of Skene's ducts cleared up the urethra A case of cervicitis treated once was not freed from gonococci In one case a reinfection of the urethra occurred from a persistent gonorrheal

proctitis Patients with salpingitis or arthritis were relieved from pain after one or two treatments Abnormal discharges rapidly disappeared Inflammatory masses subsided, but some adnexal enlargement persisted in five of eighteen cases of salpingitis The treatment is strenuous and patients with cardiovascular or pulmonary disease should not be subjected to it No serious ill effects were experienced by any of our patients

THE DIAGNOSIS OF TRICHINOSIS

WITH ESPECIAL REFERENCE TO SKIN AND PRECIPITIN TESTS

WESLEY W SPINK, MD

AND

DONALD L. AUGUSTINE, Sc.D

BOSTON

Regardless of the fact that trichinosis has been studied for more than eighty years as a human disease, it still remains often difficult to diagnose clinically Observers who have had the opportunity to study cases occurring in epidemics have noted the varying clinical course of the disease, and clinicians unanimously agree that it is the sporadic case and the milder forms of the disease which are particularly confusing and which often pass unrecognized by the attending physician¹ From recent statistical studies, it now appears that trichinosis is a common disease in this country and, further, the majority of cases seem to be of the milder forms As a specific example, Queen,² by artificial digestion of diaphragms from 344 consecutive necropsies in Rochester, N Y, found fifty-nine (17.5 per cent) parasitized with *Trichinella spiralis* None of these cases had a history of trichinosis, although some gave a vague "rheumatic" history In a second series of fifty-eight cases in Boston, sixteen (27.6 per cent) were found positive by Queen, using the same method

of diagnosis. More recently Riley and Scheffley³ reported their results of examining cadavers for trichinosis at the anatomy laboratory of the University of Minnesota Medical School. In one series of 116 cadavers, twenty (17.9 per cent) were positive, while in a second series of fifty cadavers ten (20 per cent) were positive.

During the past three years we have observed thirty-five cases of sporadic trichinosis at the Boston City Hospital and in the environs of Boston. The correct diagnosis of trichinosis was made in eleven of these cases when first seen. In the remaining twenty-four cases, other diagnoses were made, and trichinosis was not suspected until additional histories were obtained, further laboratory data made available, skin and precipitin tests performed, and the clinical courses of the cases closely observed. We will present a brief analysis of certain clinical aspects of these cases and also an evaluation of the methods used today in diagnosing this disease, with particular reference to the value of skin and precipitin tests.

LIFE CYCLE OF TRICHINELLA SPIRALIS

The signs and symptoms that may occur in trichinosis are best understood if a brief descriptive review is given of the life cycle of the parasite. Infected meat ingested by man is first digested in the stomach with the freeing of the larvae from their cysts. They pass into the small intestine within the first twenty-four hours, where they mature and copulation takes place. The female burrows beneath the surface of the mucosa, and as early as the fourth day larvae are deposited in the lymph spaces. Thence the young parasites pass into the blood stream, to be carried to all parts of the body. These young worms then penetrate the skeletal muscles, where further development takes place and they become encysted. Larvae may enter the circulation from the intestine for several weeks, the number rapidly declining after the first two weeks. The varied clinical course of the disease is understood when it is realized that trichinosis is a blood stream infection and that larvae may lodge in other tissues than skeletal muscle. It is only in the skeletal muscle that they develop fully. The larvae were first found in the blood of a human being in 1909 by Herrick and Janeway.⁴ Larvae, first demonstrated in the spinal fluid by Van Cott and Lintz,⁵ have been found by several other workers.⁶ Frothingham⁷ demonstrated, at autopsy, the larvae in a mesenteric lymph node, the lungs, heart, liver sinusoids, brain and pancreas. Subsequently, others found the larvae in the brain at autopsy.⁸

Graham⁹ found embryos in a section of rat's artery. Prym¹⁰ observed the living parasite in pericardial fluid, in esophageal and pharyngeal muscles, and in the bone marrow. Larvae have been recovered from the gall-bladder,¹¹ pleural exudate, milk of a nursing woman, mammary gland, placenta, pus from the external auditory canal (Salzer¹), and from the pus of a furuncle.¹ One of us (D. L. A.) has repeatedly recovered living embryos from the peritoneal fluid of infected mice, although they were not found in placentas.¹² Finally, they have been detected in the muscles belonging to the bones of the middle ear, in those of the soft palate, in the external sphincter ani, and in the muscles of the urethra.¹⁴

ANALYSIS OF THIRTY-FIVE CASES

Preliminary Diagnoses.—Following are the preliminary diagnoses made after a history had been taken and a complete physical examination done, with laboratory data incomplete: trichinosis (eleven), acute nephritis (six), "upper respiratory infection" (six), typhoid (three), pelvic inflammatory disease (three), poliomyelitis (two), gastro-enteritis (two), tuberculous meningitis (two), colitis, angioneurotic edema, erysipelas, undulant fever, tetanus, occupational conjunctivitis, influenza, peripheral neuritis, lead poisoning, scarlet fever, arthritis, hypotension, rheumatic endocarditis, syphilis and tuberculosis. The correct diagnosis of the twenty-four incorrectly diagnosed cases depended on further laboratory data, additional history, or observation of the clinical course.

Gastro-Intestinal Symptoms.—Gastro-intestinal symptoms are prominent in the disease picture, but in eleven of the thirty-five cases, or 31.4 per cent, they were entirely absent. Table 1 shows the symptoms that were present in twenty-four of the cases. Aldridge¹ reported an epidemic of twenty-nine cases, and, in twenty, gastro-intestinal symptoms were absent.

In a few cases the time interval was known between the ingestion of the infected pork products and the onset of gastro-intestinal symptoms. In four cases the onset was within twenty-four hours and in three cases within forty-eight hours. Diarrhea lasted eight weeks in one patient and seven weeks in a second. One patient had nausea and vomiting for four and one-half weeks. In a majority of the cases it was striking how acutely the gastro-intestinal symptoms began and how abruptly they ended.

One of us (D. L. A.) has observed the disease in a pig fed trichinella larvae. Seven months later the animal was fed larvae again, and a violent but short-lived diarrhea ensued of from one to two days' duration, then the animal appeared symptom free. It appears that the animal's gastro-intestinal tract was "sensitized" following the first infection and rapidly expelled the worms after the second infection. This is in accord with the experimental work of Ducas¹⁵ and McCoy¹⁶.

It is possible that some of the diarrhea and gastrointestinal upsets seen in patients, which are not followed by other symptoms, occur in persons who have had a previous trichinosis infection

Muscle Pains and Aches—There were twenty-six of the thirty-five patients who complained of muscle pains and aches during the course of their infections. It is significant that four patients had diarrhea but no muscle pain, and thirteen patients had muscle pains but no diarrhea. Of the thirteen patients without diarrhea, five had nausea and vomiting.

Eye Signs and Symptoms—The eye signs and symptoms are of importance in the diagnosis of trichinosis. Wetz¹⁷ explains the facial edema on a basis of toxicity

TABLE 1—Gastro-Intestinal Symptoms Present in Twenty-Four of the Thirty-Five Cases of Trichinosis

Symptoms	Number of Cases
Diarrhea	12
Abdominal pain and cramps	7
Vomiting	7
Nausea	6
Constipation	3

and local obstruction. The edema of the eyelids and face may simulate sinusitis.¹⁸ Carter¹⁹ presents an excellent discussion of the ocular manifestations of trichinosis. Table 2 shows the signs and symptoms that we have observed. In our series there were nineteen patients with signs and symptoms referable to the eyes, while in sixteen they were absent.

Chills and Fever—Much has been written concerning the temperature in trichinosis, it has been described in detail by Blumer.²⁰ The temperature curve is not unlike that of typhoid, declining by lysis. The accompanying chart illustrates the temperature, pulse and respiration in two patients with a moderately severe infection. Eight of our patients gave a history of chills.

Skin Manifestations—The skin manifestations in trichinosis are relatively uncommon and seldom commented on. Two patients had a maculopapular eruption on the abdomen closely resembling "rose spots." Two others had an erythematous lesion not unlike that found in scarlet fever. There was one case each of erythema multiforme and furunculosis. In one patient small, elevated, erythematous lesions developed under the skin of both palms.

Respiratory Signs and Symptoms—The respiratory signs and symptoms occurring in trichinosis have been described by Minot and Rackemann.²¹ Nine of their cases (88 per cent) "showed respiratory signs or symptoms, or both, severe enough to lead to a serious consideration or actual diagnosis of a purely pulmonary condition during the first few days the patients were in the hospital." MacKenty²² had cases presenting severe edema of the larynx, and intubation was necessary in one. In our series, two patients had a cough productive of bloody sputum, two had dyspnea, presumably due to the invasion of the diaphragm and

intercostal muscles by larvae, two had a severe cough, one had râles at the right base, and two had pain on respiration.

Cardiovascular Complications—The cardiovascular complications occurring in trichinosis are taken up in detail elsewhere.²³ Myocarditis is one of the most serious complications. It appears to be related to the invasion of the myocardium by larvae.²⁴ In our series of thirty-five cases there were two deaths with a complicating myocarditis, one proved at autopsy. The reaction in the cardiac muscle is not specific. It is an active, cellular infiltration, usually focal, but distributed throughout the myocardium with the production of necrotic and fragmented fibers. Death from myocarditis usually takes place between the fourth and eighth weeks. Dyspnea occurred in two patients because of myocardial failure. In seventeen cases, from one to five electrocardiograms were taken. Three patients showed evidence of myocardial changes with inversion of the T waves, especially in lead 2. These changes were not permanent. Another case showed a transient intraventricular block, and two others presented marked right ventricular preponderance.

In one patient a permanent right hemiplegia developed during the course of the disease. One had a complicating thrombophlebitis of the saphenous vein of the lower leg.

Cheney²⁵ has called attention to the occurrence of extreme hypotension in trichinosis. In twelve of our patients a hypotension developed with a systolic pressure of less than 100 mm of mercury and a diastolic pressure as low as 38. The average diastolic pressure in these twelve cases was 50 mm of mercury.

Neurologic Signs and Symptoms—Since larvae are found in the spinal fluid and have been observed in the brain, it is not unusual to see cases presenting neurologic manifestations. Hassin and Diamond⁸ describe a case of encephalitis in which the parasite was

TABLE 2—Ocular Signs and Symptoms Observed in Nineteen of the Thirty-Five Cases

Signs and Symptoms	Number of Cases
Puffiness of eyelids	17
Injection of conjunctivae	6
Pain on movement or pressure	3
Photophobia	3
Burning and itching	2
Hemorrhage into sclerae	1
Retinal hemorrhage	1

recovered from the brain at autopsy, and Meyer⁹ reports cases simulating meningitis. In two of our patients there was absence of deep reflexes, absent muscle pains and signs of an acute infection, and the diagnosis of poliomyelitis was made. A third patient had a stiff neck, drowsiness became a symptom, and there were signs of an acute infection. Meningitis was the tentative diagnosis.

Sources of Infection—The sources of infection were learned in fifteen cases, as follows: cooked pork sausage (six), pork chops (three), raw pork sausages (two), boiled ham (two), uncooked salt pork (one), and raw pork sandwiches (one).

White Blood Cell Count and Eosinophilia—Much has been written concerning the white blood cell count and eosinophilia in trichinosis since Brown²⁶ first called attention to their diagnostic importance. The white blood cells in trichinosis are not greatly increased. In our cases they ranged usually between 7,000 and 17,000 cells per cubic millimeter, in one case they reached 34,000 per cubic millimeter. As is well recognized, the occurrence of an eosinophilia in the blood of a suspected case of trichinosis is the most helpful aid in diagnosis. Twenty-two of our cases, or 62.8 per cent, were first diagnosed trichinosis because of the presence of an eosinophilia. One patient had 89 per cent eosinophils. Every patient except three had an eosinophilia when the blood was first examined. A count of 4 per cent may be considered the upper normal limit. In the three patients who did not have an eosinophilia, secondary infections were present. One had an ulcer on the foot, the second had a complicating furunculosis, and the third had bronchopneumonia. Elsewhere,²⁷ attention has been called to the effect of

The daily temperature, pulse and respiration in two cases of trichinosis

secondary infections on the eosinophilic level in trichinosis. In two of the foregoing cases the secondary infection subsided, and simultaneously there was a rise of eosinophils in the blood. The third patient died of pneumonia. Eosinophilia in trichinosis usually begins in the second week, and sometimes not until the third week of the infection, reaches its height in the third to fourth weeks, and then gradually declines. It may persist for several weeks and, in slight degrees, for months. It is commonly held that the eosinophilia is absent during the early stages of the disease and declines rapidly in fatal cases a few days before death. One of us (W. W. S.) has observed in animal experiments that the eosinophilia does not occur until the muscles are invaded by the parasite.

Skin and Precipitin Tests—Serologic and skin tests have been employed only recently in the diagnosis of

trichinosis and have been found of great value in doubtful cases. Bachman²⁸ demonstrated with laboratory animals that precipitins can be detected about the thirtieth day after infection, whereas a delayed type of skin reaction was produced within a week after infection. Stoll,²⁹ Hunter,³⁰ and Swineford and Waddell³¹ have reported successful applications of these tests in a few cases of human trichinosis.

In a critical study of the value of such tests in diagnosing trichinosis, Augustine and Theller³² confirmed the results of Bachman with animal experiments. They also found the precipitin test to be reliable in detecting established trichinosis in swine and man. False positives were obtained in individuals who had recently received quinine treatment for malaria. Certain of the arsenical compounds used in treating syphilis, and corrosive mercuric chloride also appear to affect this reaction in a similar manner. The skin test was found to be positive about the fourteenth day of infection and was of the immediate type in both swine and human beings. There is no evidence that the presence of other parasites influences either of these reactions.

Recently McCoy, Miller and Friedlander³³ used a somewhat different antigen from that employed by the authors previously mentioned. Their results were essentially similar to those of Augustine and Theller.³² According to McCoy and his associates, about 90 per cent of persons ill with trichinosis will show a positive skin test to the trichinella antigen.

More recently, Kilduffe³⁴ reported the use of the skin test on thirty-three individuals with trichinosis. His conclusions to the effect that it possesses no advantages over the finding of an eosinophilia must be discounted, because he used an antigen in a dilution of 1 to 100, read the reactions at the end of twenty-four hours, and classified his reactions according to the method used by Bachman in laboratory animals.

Maternowska³⁵ recently reported that the skin test in man and animals was specific, and Friedlander,³⁶ after several years' experience with the skin test at San Francisco and Rochester, N. Y., considers it a valuable aid in the diagnosis of the disease.

The antigen used in our series of cases was prepared according to the method of Bachman.^{28b} The skin test was made by injecting 0.1 cc. of a 1:10,000 dilution of the trichinella antigen intradermally into the inner surface of the forearm. A similar amount of Coca's solution (the diluent of the antigen) was injected into the other arm as a control. The test was read within five minutes. Typically, a blanched wheal makes its appearance within this time. This rapidly increases in size until after one hour it has reached its maximum of from 10 to 20 mm. in diameter. Occasionally pseudopodia are formed, running out from the wheal. Also a pronounced erythema usually appears promptly about the wheal. After twenty-four hours the reaction

may have disappeared entirely, but usually a faint, pink, circumscribed area from 5 to 8 cm in diameter remains at the site of the reaction

In the present series, thirty-three of thirty-four patients gave positive skin tests. One patient was in a moribund condition and gave a negative skin test but a positive precipitin test. Eight patients gave negative skin tests on entry to the hospital, but from two to three weeks after the onset of the illness the tests became positive. This test has proved of great diagnostic value in patients who have acute gastro-enteritis, with skin tests at first negative for trichinosis but later becoming positive. A positive skin test has been noted as early as the fourteenth day after infection, but in most cases a positive reaction was not obtained until the seventeenth day. We have not found the size of the skin reaction, or the rate with which it appears and decreases, to bear a constant relationship to the severity or duration of a trichinosis infection. It has been observed that a few apparently normal individuals give positive skin tests. This may be explained by the fact that some people are hypersensitive to any protein injected into the skin, or the reaction may be due to a previously unrecognized trichinosis. Theiler, Spink and Augustine³⁷ observed that patients may show a positive skin reaction seven years after an infection with *Trichinella spiralis*. Thus, it is not possible by means of the skin test to distinguish between acute trichinosis infections and those which occurred some years previously. It was also observed that precipitins may be present in the blood serum after that length of time but are demonstrable only in flocculation tests.

The precipitin test is performed by overlaying 0.5 cc of serum in a small tube with an equal amount of a 1:100 dilution of the antigen. A control test is run in a second tube with the same amount of serum overlaid with Coca's solution. The tubes are placed in a water bath at 37.5 C for one hour. A positive test shows a white ring at the junction of the antigen and serum. Occasionally the ring may be formed immediately, and more often within an hour.

The precipitin test was performed in only nineteen of the cases, and it was positive in all of them, as was the skin test. The precipitin test usually became positive at the end of the fourth week of the infection. So far, we have not found a constant relationship between the duration or severity of an infection and the size of the ring or the time it takes for it to form. It has been noted that in a few doubtful cases the control tube may show a ring as well as the tube with the patient's serum and antigen. We are unable to explain this. The skin tests in these cases were also doubtful. We have continued to do precipitin tests on a few of the patients included in this series and have noted no change in the appearance of the reaction one year after the infection.

Biopsies—Another diagnostic aid in trichinosis is that of excising a small piece of skeletal muscle and examining it microscopically for parasites. In thirteen of the thirty-five cases, biopsies were done. Twelve were interpreted as positive for trichinosis, and one was negative. However several showed only chronic inflammation and no parasites. We believe that the biopsy is an unnecessary procedure not only because of the uncertainty of finding parasites in a small piece of muscle but also because precipitin and skin tests are as

reliable as the procedure of biopsy, which is, of course, an inconvenience to the patient. To illustrate how difficult it is to find larvae in muscle biopsies, one of us (D. L. A.) infected a pig, and later more than eighty bits of muscle were examined microscopically without finding the parasite. It was only after the diaphragm, masseter muscles and part of the tongue were ground up and digested in artificial gastric solution that a few larvae were found in the sediment.

Spinal Fluid, Blood and Stool Examinations—Practically all textbooks of medicine and those concerning laboratory procedures mention as an aid in diagnosis the finding of larvae in either the spinal fluid, the blood or the stools. Our experience is that, in any case, such observations are rare and of little value as practical diagnostic procedures. In none of our cases were we able to demonstrate larvae in the stools. Lumbar punctures were done in three cases and no parasites were seen in the cerebrospinal fluid. In two cases a careful, unsuccessful search was made for the larvae in the blood.

COMMENT

It is emphasized again that trichinosis is not an uncommon disease. Its recognition and correct diagnosis depend on a careful history of the patient's illness. In thirteen of our cases it was learned that other members of the family were ill. The most reliable laboratory procedure is the careful study of blood smears for eosinophilia. Mildly ill persons and sporadic cases constitute a serious phase of the trichinosis problem. It is in these cases that the skin and precipitin tests are of great value. Patients with slight fever, a slight eosinophilia, and vague aches and pains extending over a period of several weeks should have skin and precipitin tests done for trichinosis. Finally, it should be remembered that trichinosis is a public health problem. The best available method for reducing the incidence of the disease is the thorough cooking of all pork products.

SUMMARY

1 Thirty-five sporadic cases of trichinosis occurring in and around Boston during the past three years were analyzed.

2 The most reliable diagnostic clinical aid in these cases was the presence of an eosinophilia.

3 The skin test usually becomes positive about the seventeenth day of the infection, and the precipitin test usually at the end of the fourth week. These tests are of especial diagnostic aid in the early stages of the disease, when they are first negative and later become positive. Mild, sporadic and chronic cases of trichinosis were often detected only by these tests.

4 Other laboratory procedures, such as searching for the parasite in the stools, blood and spinal fluid, are time consuming, and the larvae are only rarely found.

Disturbingly Lopsided—And whether any one thinks more clearly and deeply than before about the social problems that face humankind and whether people as a whole are as contented and happy as they were in simpler times may well be doubted. Invention of course is an inevitable part of science, in so far as the scientist continually has to improvise things to help his researches, but the trouble comes when business takes both science and engineering into partnership and then through mass production abetted by the psychology of modern salesmanship makes the distribution of the economic benefits disturbingly lopsided.—Cushing Harvey. *The Humanizing of Science*, *Science* 81 137 (Feb 8) 1935.

A METHOD OF EVALUATING CARDIAC PAIN IN CHILDREN

HAROLD C LUETH, MD

EVANSTON, ILL

AND

DON C SUTTON, MD

CHICAGO

Pain is a valuable symptom in the diagnosis of cardiac conditions. In angina pectoris, for example one patient may complain of a viselike constriction of the chest and another may merely experience a deep dull sensation that he dismisses as a transient numb feeling over the heart. This variation of response, as well as the different descriptions given by patients¹ makes pain an equivocal symptom. However, it is not to be expected that all patients will give the same response to a given pathologic condition nor even is it seen in the same individual at all times. Much of this apparent difficulty in the evaluation of pain can be overcome by taking a careful history and estimating the patient's sensitivity to pain by past experience.

We have long been perplexed by the child who complains of a pain over the heart. A complete history of this disorder or an attempt to make the child fully describe these sensations has often given no substantial additional information. In a few cases the diagnosis was clear after the parents gave the story of an acute chorea, an impending decompensation or an attack of arthritis, and in even fewer did an examination of the child reveal anything of note. Often a brief neuropsychiatric testing would demonstrate this symptom to be another manifestation of a "nervous" child. We were distressed, however, in a small group of children to find that this complaint was an early symptom of a severe carditis or that it ushered in a fatal endocarditis. Out of this confusion it was hoped that a means could be found to differentiate those cases in which cardiac pain was apparently a harmless symptom from those in which it was associated with an advancing pathologic process. Libman's² test appeared to fill these requirements, consequently it was used.

After a long study of this subject Libman devised a simple method of testing the pain response of a patient. Both of the examiner's thumbs are pressed against the mastoid bones, then the forefingers are slipped forward against the tips of the styloid processes. Normally, pressure over the mastoid causes no pain, which may be used as a control reading. The same amount of pressure applied to the styloid tips is painful to a few but painless to most individuals. The pressure should be applied in one direction, since rubbing the bones evokes the painful response of rubbing the periosteum. From the responses obtained from this test, Libman divided patients into different classes.

METHOD

One hundred children of the cardiac follow-up clinic of Cook County Hospital were used for these experiments. Children under 6 years of age were eliminated from this series, as it was believed that they might not fully understand the presence of minor cardiac sensations. They may complain freely of acute pain over the heart, as in an acute pericarditis, but palpitation,

tachycardia and dull aches over the heart are rarely mentioned. The series represents an unselected group of 100 children between the ages of 6 and 15, 53 per cent were boys and 47 per cent were girls, 82 per cent were white and 18 per cent were Negroes.

All children were asked three questions: "Do you ever have a pain over your heart?" "Do you ever feel anything over your heart or left chest?" When an affirmative answer was given to these questions they were asked, "What does it feel like?" When a negative reply was given to the first two questions, the child was asked whether he experienced anything over his heart that felt or sounded like palpitation. Gentle tapping with the forefinger over the precordium and lightly striking the top of a metal bedside table with the blunt end of a fountain pen were believed to be close imitations of palpitation. Since these were highly suggestive procedures, children who gave affirmative answers to the latter question were questioned closely to ascertain if the sensations they felt might actually be palpitation.

Sensitivity to pain was tested by pressure over the mastoid process and then over the styloid process. This pressure was gradually increased, depending on the response of the child. When the patient did not complain, the pressure was the maximum that could be obtained by first pressing both thumbs together and then the forefingers, thus insuring a uniform stimulus. Several physicians of the clinic repeated these tests on some of the children and obtained the same responses that we had previously recorded. Before making the test, the examiner must be certain that there is no local disease in the region of the mastoid, otitis media, mastoiditis, enlarged postauricular glands, painful scars of old mastoidectomies, and skin abrasions or lesions preclude testing that area. In one child we had to confine the test to the right side, as he had just recovered from an otitis media and a mastoiditis, but this did not hinder the experiment, in fact, his results fit in well with the others of his group.

Three classes of responses were obtained and recorded. Those children who gave no evidence of pain in either region were designated class 1. Children showing a mild response of pain, who after questioning admitted slight degrees of pain or who volunteered the remark "It hurts a little" were placed in class 2. The third class consisted of those who evinced great pain during the test or who complained so bitterly when the pressure was applied that maximal amounts could not be used. Each class was in turn divided into two groups, P, those who had cardiac sensations and A, those who had none. Activity, as noted, includes pyrexias of more than 99.4 F or pulse rates of from 110 to 130 for an average of three months or more, a recurrence of an articular inflammation, chorea or endocarditis, an increasing dyspnea or a threatening decompensation necessitating a return to the hospital or a convalescent home, or a rapid enlargement of the heart size.

RESULTS

The largest and most interesting group were the sixty-four patients who comprised class 1. Of this group, fifty-four did not complain of or notice any cardiac sensations (1 A) while ten did (1 P). Of the former group, forty, or 74 per cent, had inactive lesions, the remaining fourteen, or 26 per cent, showed activity. Unmistakable signs of activity were present in nine of the ten patients (90 per cent) of class 1 P. Three of these children had died, two of decompensated rheumatic carditis and one of bacterial endocarditis.

From the Department of Medicine, Northwestern University Medical School, and the cardiac follow-up clinic of Cook County Hospital.

² Libman, Emanuel. *Observations on Individual Sensitiveness to Pain*. J. A. M. A. 102: 335-340 (Feb. 3) 1934.

Persistent tachycardia, from 110 to 128 per minute, and a prolonged fever were present in two cases. One patient is still convalescing from an acute endocarditis, another has had a prolonged pyrexia for months, and a third showed a recent extension to the aortic valve from an old mitral stenosis, accompanied by an enlargement of the left heart border. A youth with hypertension has maintained a systolic pressure of more than 190 mm of mercury for the past two years. There is but one case in group 1 P in which no ascertainable signs of an active rheumatic infection are present.

Class 2 gave the widest distribution of cases to its subdivisions. Eighteen of these children, or 72 per cent, experienced no pain or distress whatever, six had active lesions, while twelve were inactive. Only seven, or 28 per cent, noted cardiac sensations (2 P), and the distribution of activity and inactivity was nearly equal, that is, three and four.

Eleven patients formed the last group, or class 3. As these were the children who reacted most violently to painful test stimuli, it is not surprising that all but one complained of cardiac distress. Four of these ten (3 P) showed active carditis, while six did not. The only one who did not complain of cardiac distress (3 A) had an inactive cardiac lesion.

The relationship of cardiac sensitivity and activity for the entire group is noteworthy. Twenty-seven per cent of the patients complained of cardiac sensations, and active endocarditis was seen in 36 per cent of the cases of this series.

COMMENT

Numerous objections to this type of experimentation naturally arise. Some might object that leading and too pointed questions were asked the children concerning their cardiac symptoms. True as this might at first seem, any considerable experience with children will show that great ingenuity is required to get a good history. The imitation of palpitation by tapping on the patient's chest was used with such good results in reticent or illiterate adult patients that it was tried on children, among whom it seems to enjoy a similar success. Uniform pressure was applied in all but a few cases, and even when different examiners tested the same patient a uniform response was always noted. This pain stimulus, therefore, must be approximately equal in all tests.

Classification of the groups on the basis of response was arbitrary, and consequently some difficulty arose concerning "borderline" cases. As class 1 and class 3 were quite definitely fixed, most of the questionable cases were put in class 2. This may in part explain the great variety of response found in the latter group. Also, activity and inactivity were more or less definitely separated. A fever with a mean temperature curve of more than 99.4 F for a period of three months, or a pulse rate of from 110 to 120 over the same period of time, was accepted as an active rheumatic infection. A spread of the valvulitis to a new valve, a change in cardiac contour with the appearance of new murmurs or an alteration of heart tones, the presence of irregularities, such as gallop rhythm, dropped beat or auricular fibrillation, was evidence of an active carditis. While admitting that we may have overlooked cases of silent endocarditis from the list of active cases, we also wish to call attention to the great difficulty in their diagnosis.⁴

Pain in rheumatic heart disease of children has been variously discussed by different authors. Most of them mention pain and give the classic description of either the pain of an acute pericarditis or that of the decompensated heart.⁴ Coombs⁵ in his lucid monograph of this disease mentions in addition to the types just cited an anginal type, seen presumably in older children and adults, as well as milder dull pains, which he attributes to myocarditis. On the whole, there appear to be few references to "heart pain" in children; the work of Swift and Hitchcock⁶ is the exception in this respect. They find it to be a common symptom in the child with a rheumatic fever and caution the practitioner that he must inquire after this symptom in children or it will be missed. The acute arthritic pains are often so severe that the mild cardiac pains are often overlooked. They found the intensity of precordial pain to be roughly proportional to the severity of cardiac damage. Individual sensibility to pain in this work was determined entirely by subjective means.

Libman's test is unique in that it makes it possible, in a number of cases, to determine a subjective symptom—pain—in an objective way. It is of course impossible to consider every complaint of every child, especially of those who are neurotic, and this pain sensitivity classification was therefore decided on. Unlike Libman, we did not call those children hypochondriac who experienced no pain on pressure over the bony prominences, as they constituted 64 per cent of the entire group. They were merely called class 1. The presence of heart sensations, i. e., pain or palpitation, in the group who normally do not complain of pain on pressure over a bony region is usually accompanied by active cardiac disease in the majority of cases. Despite the seemingly small number of cases in class 1 P, the large proportion showing active disease, as well as the degree and the severity of the lesions, seems to establish this rule. Only three deaths occurred in this entire series, all of which came from this subdivision. Even the other two groups in which cardiac pain was noted showed a much higher percentage of cardiac damage than any single group not presenting this symptom. A total of thirty-six patients had demonstrable pathologic changes of the heart, while a total of twenty-seven patients complained of precordial symptoms, again illustrating the close parallelism between cardiac damage and pain.

The disposition of the other cases is not so conclusive. In class 1 A about three fourths of the cases are inactive. This is about what is to be expected in a group of children who tolerate pain well and have no sensation about the anterior chest wall. Perhaps those cases which are active in this group represent hearts in which the rheumatic infection is progressing at such a slow rate that the pain mechanism is not involved. Class 2 presents such widely divergent results that no analysis is attempted. This is not surprising when it is remembered that it is not actually a class but merely an aggregation of those cases which fit in neither class 1 nor class 3.

Those children who were hypersensitive, class 3, experienced pains about the heart in 91 per cent of the cases. Pain over the heart (3 P) was about equally

⁵ White, P. D. *Heart Disease*. New York: Macmillan Company 1932.
⁶ Swift, H. F. and Hitchcock, C. H. *Diseases of the Heart*. New York: Macmillan Company 1933.

⁵ Coombs, C. F. *Rheumatic Heart Disease*. New York: William Wood & Company 1934. pp. 144-153.

⁶ Swift, H. F. and Hitchcock, C. H. *Cardiac Pain in Rheumatic Fever*. J. A. M. A. 60: 678-683 (March 3) 1928.

divided between those having active disease (four) and those having none (six), thus giving rise to two explanations of the origin of pain in this class. In the first group it was probably the end result of active infection over a long period of time which made the child not only sensitive to pain over the heart but to all painful stimuli while the second group may be considered neurotic children without any active lesion. The single patient in class 3 A is also of this type. As might be further anticipated, seven, or 63 per cent, of the entire group had no demonstrable pathologic condition.

CONCLUSIONS

1 Children who do not experience pain after a simple pressure test usually do not complain of cardiac pain.

2 Those who complain of cardiac pain and not of pain after the pressure test almost always have demonstrable cardiac disease.

3 Those who complain of severe pain following pressure on a bony area usually complain of cardiac pain and often do not have any active cardiac lesion.

4 In the course of an acute rheumatic infection, cardiac pain and palpitation are valuable symptoms for the diagnosis of carditis. Unless they are specifically sought for, they will be frequently overlooked.

636 Church Street—30 North Michigan Avenue

STERILITY AND THE X-RAYS

MAX HUHNER, M.D.
NEW YORK

Every dermatologist knows and has known for a long time that the x-rays in sufficient doses interfere with the spermatogenic function of the testicle or destroy it entirely. Consequently, when he uses this modality about the genital organs for therapeutic purposes he is careful to protect these organs from any possibility of being affected by the x-rays.

In my practice, however, I have had a few patients who, in spite of such protection, became sterile although previously fertile, and, as far as could be determined by the most painstaking investigation, this was the sole cause for the sterility. I would emphasize that the cases referred to were not treated by general practitioners or those who only occasionally employ the x-rays but generally by expert and experienced dermatologists, fully aware of the danger, and, according to the patients' statements, adequately protected the genitals. In most of the cases the x-rays had been given for some dermatologic condition about the thighs or perineum. As just mentioned, some of these patients had been of proved fertility before the application of the rays, either by reason of having impregnated their wives or from condom examinations, yet after such application condom specimens were found either to be absolutely devoid of any spermatozoa alive or dead or contained but few live or dead spermatozoa.

Purely as a result of this clinical experience, and ignoring for the time being any theoretical considerations, it has occurred to me that perhaps the protection usually given is not adequate enough and that somewhere there might be a leakage which allows the rays to get at the testicle in spite of such protection.

I will therefore report a few cases in which the patients had been perfectly fertile before and now have

azoospermia, and then a few cases in which the patient came on account of sterility and, as far as could be determined, there was no other reason for the azoospermia except a previous application of the x-rays. In the second series of cases, however, there is no scientific proof that the organs were normal previous to the treatment, as no condom examinations had ever been made before such treatment.

CASE 1—J. L. S. consulted me for sterility in September 1925. At that time he had been married two and a half years and his wife had a miscarriage a year before as the result of an automobile accident. Since then he had received roentgen treatments from a prominent dermatologist for a period of five months for psoriasis. The dermatologist informed me that protection had been used and that the dose of x-rays was too small to influence the testicles. Nevertheless, condom specimens examined by me and others were absolutely negative for spermatozoa. He never had a venereal disease. Feb. 6, 1926, after several negative condom examinations, I aspirated the right testicle and found no spermatozoa in the aspirated testicular fluid showing that the azoospermia was testicular in origin. All condom examinations were made within an hour after coitus and after ten days' continence.

CASE 2—R. L. was seen July 15, 1932, for sterility. In 1927 he received roentgen treatments for ringworm near the testicle without any protection whatever. Nevertheless a Huhner test (searching for spermatozoa in the female genitals after coitus) made three years later by a competent gynecologist showed numerous live spermatozoa in the female genitals. Four months after this examination, in January 1931, he again received roentgen treatments by another dermatologist for a rash on the abdomen and side, but now the testicles were protected. Six months after these treatments he came to me and a condom specimen showed absolutely no spermatozoa, neither of course did a Huhner test on his wife. I put him on increasing doses of the anterior lobe of pituitary extract, which he took for about six months, but spermatozoa never reappeared in the specimens. In a follow-up letter he informed me that another condom specimen examined by Dr. Huhner in Washington also proved negative.

CASE 3—This patient came for sterility in 1933. His condom specimens showed a few dead spermatozoa as well as a few very lively ones. It seems that the spermatozoa produced by the testicles were about normal but that their number was markedly diminished. The specimens were examined about one and a half hours after coitus and after ten days' continence. His history shows that his semen as examined several times by a prominent gynecologist in 1932, was absolutely normal. He then submitted to six roentgen treatments to the perineum for pruritus and after that the condom specimens were abnormal. The dermatologist had used a protective device to the testicles. I put him on increasing doses of the anterior lobe of pituitary extract with the result that another specimen examined five months later was absolutely normal. All know, of course, that even in normal cases there are variations with regard to the number of spermatozoa found in a specimen and that once in a while the number may be far below normal, but in this case repeated specimens taken each time after a long period of continence showed a marked diminution in the number so that the condition cannot be considered accidental.

CASE 4—N. R. was seen in 1925 for sterility. At the time he had been married five years but his wife had had a miscarriage four years before his visit to me. He never had any venereal disease and coitus was normal. About one year after his wife's miscarriage he received roentgen treatments once a week for a period of five months for a skin disease in both groins. The testicles were protected. Several condom specimens examined within a short time after coitus and after long periods of continence always showed absolute azoospermia.

DOUBTFUL CASES

CASE 1—M. S. consulted me for sterility in 1931. He had been married four and a half years, but during the first year he employed contraceptive measures. He never had venereal disease or a swollen testicle. Coitus was normal. About a

year after marriage a dermatologist applied x-rays to the testicle for a skin disease. Altogether he had five treatments. Repeated condom examinations thereafter were negative for spermatozoa and no spermatozoa were found by me on aspirating the testicles. He did not reply to my follow-up letter.

In this case, however, it is not known whether the patient had been sterile prior to the roentgen treatments as he had employed contraceptive measures till then. It is true that there were not present any of the usual causes for azoospermia, nevertheless this must be considered a doubtful case.

CASE 2—J F had had three roentgen treatments to the scrotum in 1925, although, he said, the testicles were protected. A year later he married and for the first three years used contraceptive measures. His wife then went to Dr Vineberg for sterility, who found azoospermia in a condom specimen and referred him to me. Several condom specimens examined by me showed the same condition. The patient never had any venereal disease or any other causative factor to account for the sterility. Here again, as a condom specimen was never examined prior to these treatments, a definite conclusion cannot be drawn.

COMMENT

The number of cases recited is few, but it is only recently that I have investigated this matter, and many of my cases of male sterility date back many years, so that it was impossible to get in touch with them. I have no doubt, however, that there were more cases, especially as my histories show many cases of azoospermia in which no cause could be found for the condition. Of course some of these were probably congenital in origin, but there might have been some due to the cause under discussion, but as before said, I could not communicate with the patients. It is also suggestive to note that in many of these cases the testicles as palpated were not small or atrophic but appeared perfectly normal.

Ordinarily it would have been more scientific to wait till I had obtained a larger number of cases to report, but sterility is such a very serious condition often causing the most intense suffering and unhappiness and at times leading to divorce, that I consider it more humane to call attention to this warning at the earliest possible time rather than wait for more cases to develop.

It must be recognized that different testicles react differently to the influence of the x-rays, some being much more sensitive than others, so that what might be adequate protection in some cases would not at all be for others. While I was discussing the condition with a prominent and experienced dermatologist, he informed me that he used a heavy piece of rubber for protection and that although he admitted that some of the x-rays might penetrate this rubber sufficiently to develop a film, not enough would penetrate to affect the testicles. However, in discussing the matter with an expert roentgen therapist, I was informed by him that an ordinary piece of rubber was not, in his opinion, adequate protection, and in order to obtain such protection it was necessary to add a lead plate as well as an aluminum plate to the device.

It might be objected that in the foregoing discussion no mention is made of the dosage of x-rays received by the patient. In the first place, in most of the cases reported, all my information came through the patient himself, who obviously could give no information on this point. But the question of dosage is entirely aside from my purpose in this paper. As before said, the cases were treated by expert dermatologists who at the time considered the dosage given plus the local protec-

tion adequate enough to prevent any testicular damage, and it is my object to show that at times this is not the case.

CONCLUSIONS

In some cases the testicles are so sensitive to the action of the x-rays that doses which are ordinarily considered harmless may cause sterility. The protective devices ordinarily employed to shield the testicles from the action of the x-rays when applied near the genitals may not be adequate enough to prevent such harm.

ENTEROGENOUS CYSTS OF THE DUODENUM

REPORT OF A CASE AND REVIEW OF THE LITERATURE

CLARENCE C. GARDNER, JR., M.D.

AND

DERYL HART, M.D.

DURHAM, N. C.

Cysts and diverticula of the gastro-intestinal tract have been noted frequently in the literature. They represent a congenital abnormality that presents a problem to the clinician in diagnosis and to the surgeon in treatment. Although diverticula of the duodenum are not infrequent, cysts of the duodenum have been noted in the literature only six times. The present case is reported in the belief that every additional report of a condition so rare may be utilized in obtaining a more prompt recognition and better understanding of future cases.

REPORT OF CASE

History—H. S., a white girl, aged 15 years, admitted to the medical service of the Duke Hospital, Sept. 21, 1931, complained of intermittent attacks of abdominal pain and vomiting of twenty-two months' duration. Her birth and development had been normal, although she had always been frail. At the age of 6 months and also at 2 years she had attacks of unexplained hematemesis and melena. At the age of 3 years she complained of vague abdominal pain and on one occasion passed gross blood in the urine. These vague abdominal pains continued intermittently, and when she was 7 the appendix was removed. Ten days after this operation severe abdominal pain recurred, felt most acutely in the right flank and upper part of the abdomen. She was at first thought to have a kidney stone, although this diagnosis was later changed to tuberculosis of the kidney. After several months all symptoms disappeared, and she remained in good health for five years. Twenty-two months prior to admission she began complaining of intermittent attacks of dull aching pain in the right upper part of the abdomen, often accompanied by vomiting. Associated with these she felt a lump in the upper part of the abdomen on the right side, which disappeared between attacks. These attacks lasted for from one to two days and recurred at intervals of from seven to thirty days up to the time of admission. The pain was never cramping nor was there any characteristic radiation. It was thought that the vomitus was bile tinged at times. It had never contained blood since the attacks in infancy, and food residue had not been noted. She had never been jaundiced. There had been no urinary or menstrual symptoms. Bowel movements had always been regular and there had been no blood, pus or mucus in the stools.

Physical Examination—The temperature was 37.2 C (99 F), the pulse 92, the respiration rate 22, and the blood pressure 118 systolic, 80 diastolic. She was 152 cm. tall and weighed

From the Department of Surgery, Duke University School of Medicine.

416 Kg. She was rather small but normally developed and was in no discomfort. The skin was pale and somewhat sallow but not jaundiced. There were palpable axillary and epitrochlear lymph nodes. The abdomen was flat and moved freely with respiration. Under the right costal margin there was a slight visible fullness. In this area on palpation an indefinite moderately tender mass in the region of the gallbladder could be felt. It seemed to be smooth, about 10 cm in diameter, and did not descend with respiration. It could not be felt in the flank. The abdomen otherwise was normal and the remainder of the general physical examination was negative.

The blood showed a hypochromic anemia (red blood cells 4,460,000, hemoglobin 85 Gm., 60 per cent Sahli color index 0.68, white blood cells 7,400). The Wassermann reaction of the blood was negative. The urine showed no abnormalities. Repeated stool examinations were negative for blood, pus, mucus and parasites.

Relation of the cyst to the duodenum and stomach. The cyst occupies a submucous position in the lower and anterior wall of the duodenum and bulges into the duodenal lumen, compressing it into a narrow slit.

A plain roentgenogram of the abdomen showed a rounded, smooth, soft tissue mass on the right side of the vertebral column extending from the eleventh dorsal to the third lumbar vertebra. On fluoroscopic examination the mass did not descend during inspiration. A pyelogram on the right side showed normal kidney calices and demonstrated no connection between the mass and the kidney. Roentgenograms of the barium sulphate filled stomach and duodenum showed no abnormality. With a barium sulphate enema the colon filled normally and showed the hepatic flexure to be pushed down by the mass. Cholecystograms showed a small normally filled gallbladder, which contracted well after the fat meal.

Clinical Course—The patient remained in the hospital nine days, during which time she was afebrile and free from all symptoms. After the first day the mass in the right upper part of the abdomen, which was indefinite on the first examination, could no longer be felt. As an operation was not agreed on, she returned home, October 1.

Readmission—The patient was readmitted, November 11, with a history of having had four days after discharge, a severe attack of pain in the right upper part of the abdomen,

with repeated vomiting of two days' duration. Since then she had had repeated less severe, though similar, attacks. Examination showed essentially the same condition as on the first admission. An indefinite mass in the right upper part of the abdomen could be felt as on the first examination. Operation was performed, November 21. The preoperative diagnosis was choledochus cyst.

Operation—The abdomen was opened through a right rectus incision. General abdominal examination was negative except for the right upper quadrant. The upper third of the duodenum was markedly dilated and it was impossible to empty the dilated part either into the stomach or into the lower part of the intestine. The distended area felt like a cyst. This cystic mass was surrounded by the vessels and muscles of the duodenum and seemed to protrude through the pylorus and into the lower 2 or 3 cm of the stomach. The remainder of the stomach was normal in size and appearance. From external examination it was impossible to determine the relationship of the duodenal lumen to this cystic mass. The gallbladder was not distended and the common bile duct was normal in size. The stomach was opened just above the pylorus to permit inspection of the interior of the stomach and duodenum. The lumen of the duodenum was then seen to lie on the upper dorsal side of the cyst as a flattened mucous membrane lined channel, and the cystic mass seemed to lie within the duodenal wall, as shown in the accompanying illustration. It was evidently impossible to excise the cyst, which was so closely associated with the wall of the duodenum and the pancreas, and possibly with the pancreatic duct, the ampulla of Vater, and the bile duct. The cyst was aspirated and a thin, clear, slightly greenish fluid was obtained. This suggested the presence of bile pigments, although the fluid did not have the appearance of bile and on subsequent chemical examination it was negative for bile pigments.

The cyst was opened from within the duodenum, the incision going through the mucous membrane, submucosa, fibromuscular wall of the cyst and the mucous lining of the cyst. Examination of the interior of the cyst showed no communication with the lumen of the intestine. The muscular wall of the intestine apparently went entirely round the cyst and the duodenal lumen. Working from within the stomach an anastomosis, which would admit two fingers, was made between the cyst and the duodenal lumen. The incision in the wall of the stomach was then closed. The abdominal incision was closed in layers with catgut, silk worm gut stay sutures and silk for the skin.

Postoperative Course—Recovery after operation was uneventful and the patient left the hospital free from symptoms on December 10. She was readmitted to the hospital twelve days later having had another attack similar to those suffered before operation. This began on the day prior to admission and lasted for three days. Two weeks later she had another attack of twelve hours duration with a chill and elevation of temperature to 38 C (100.4 F) and a pulse rate of 128. Two days later an erythematous patch appeared on the left cheek and numerous lesions of herpes simplex on the lips. These lesions lasted about a week, during which time she was afebrile and without abdominal symptoms. She was discharged free from symptoms Jan 21, 1932. Her mother wrote, Jan 4, 1934, that since the last date she had been free from all digestive symptoms except for an attack of pain in the right upper quadrant and vomiting of twelve hours' duration in November 1932.

REVIEW OF PREVIOUSLY REPORTED CASES

Sanger and Klopp¹ in 1880 reported the case of a new-born child who had died during a difficult delivery. The viscera were transposed. The abdomen contained five cysts, one from an accessory liver, one from an accessory bile duct and three from the intestine. One of the latter had its origin in the duodenum. This duodenal cyst was about the size of a walnut and microscopically was composed of all the normal layers of the duodenal wall.

¹ Sanger, M. and Klopp, A. Zur anatomischen Kenntniss der angeborenen Bauchleysten. Arch. f. Gynak. 16: 415 1880.

Roth² in 1881 reported the case of a new-born male infant who died a few minutes after delivery. The abdomen was tremendously distended and contained a large pedunculated thin walled cyst arising in the duodenum. The cyst did not communicate with the lumen of the intestine. The cyst wall was found to contain all the layers of the normal intestine. This patient also had an enterogenous cyst in the right posterior mediastinum situated close to the esophagus and evidently derived from it.

Meyer³ in 1919 reported the case of a female infant, aged 3 weeks. Birth was normal and first feedings were retained. At the age of 13 days she began vomiting after each feeding and when seen at the age of 3 weeks she was emaciated and dehydrated and was not retaining any of her feedings. No abnormal abdominal changes were noted. The diagnosis of pyloric stenosis was made and the child died four days later, no operation having been performed. At autopsy the pylorus and first portion of the duodenum were found dilated and in the medial wall of the duodenum was a cyst the size of a hen's egg. This extended from the pylorus to the ampulla of Vater and bulged into the lumen of the duodenum obstructing it. No communication between the lumen of the duodenum and that of the cyst could be demonstrated. Microscopically the cyst wall was composed of the normal layers of intestine, and the cyst was seen to occupy a submucous position in the duodenal wall.

Waugh⁴ reported the fourth case in 1923. The child, a female infant, aged 19 days, had been regurgitating food immediately after feedings since birth and had been steadily losing weight. In the two or three days prior to examination she had not retained any of her feedings. On examination she was found to be undernourished. A firm, indefinitely rounded mass could be palpated on the right side of the abdomen extending from the iliac fossa to the costal margin. At operation a cystic mass presented on the outer surface of the colon and displaced the hepatic flexure and transverse colon anteriorly. The peritoneum lateral to the hepatic flexure was incised and a retroperitoneal cyst was shelled out as far as the midline. Here the cyst was found to be intimately connected with the posterior wall of the duodenum. Examination of the duodenum showed its second portion stretched like a ribbon across the anteromedial aspect of the cyst. The cyst was opened, no communication was demonstrated with the lumen of the duodenum and the cavity of the cyst was packed with gauze, which was brought out through the abdominal incision. Following removal of the gauze the child did well for six weeks, at which time it began to vomit again. One week later at a second operation the cyst was found to have refilled. It was evacuated and its wall sutured to the aponeurosis of the abdominal wall. The child died six days later of pneumonia. Microscopic section of a portion of cyst wall removed at the first operation showed it to be composed of an inner circular and outer longitudinal muscular coat.

Maddox⁵ reported the fifth case in 1927 in a 3 months old child whose sex was not recorded. Since the age of 6 weeks the patient had vomited following feedings and had not gained in weight. On examina-

tion the child was found to be undernourished and dehydrated. Gastric peristalsis was visible in the epigastrium, and a movable mass 6.25 cm by 4.3 cm was palpable in the region of the pylorus. At operation the first portion of the duodenum was found to end in a large fusiform cystic tumor the size of a goose egg. From the lower pole of this mass emitted the attenuated third portion of the duodenum. The child's condition was too poor to permit further operation and it died sixteen hours later. At autopsy the mass seen at operation was found to be a thin walled cyst, which projected into and obliterated the lumen of the duodenum. Microscopically its wall was composed of an inner layer of poorly developed columnar epithelium, a middle layer containing scattered plain muscle fibers with no differentiation into circular or longitudinal layers and an outer adventitious coat.

Smith⁶ reported the sixth case in 1930. The patient, a 2 weeks old female infant, had vomited after practically every feeding since birth and had not gained in weight. The vomitus did not contain bile, and greenish stools had been passed. Examination revealed an undernourished baby with a distended abdomen. At times there was visible gastric peristalsis and it was thought that a tumor was present beneath the right costal margin. A tentative diagnosis of congenital pyloric stenosis was made. At operation two weeks later the first portion of the duodenum was found to be enormously distended. It was decided to perform a duodenojejunostomy. When the supposedly distended intestine was incised a large amount of serous fluid escaped, revealing the true condition—a cyst in the anterior wall of the duodenum. There was no communication between this cyst and the intestinal lumen. The stomach was opened and dilators were passed with ease through the pylorus and the upper part of the duodenum. The stomach was closed and the cyst drained externally. The child died one week later. At autopsy the cyst was found to be reduced to the size of a pea.

ETIOLOGY

As emphasized by Evans,⁷ there can be little doubt that cysts which reduplicate all the layers of the normal intestine have their origin in defects of development of the intestinal tract. Lewis and Thyng,⁸ in a study of the embryo of the pig, rabbit and man, regularly found knob-like diverticula along the entire intestinal tract. These diverticula appeared first in the duodenum and later along the entire small intestine, being most numerous in its terminal portion. In only one embryo were they found in the colon. Similar diverticula were also found along the bile ducts and probably explain the origin of the choledochus cyst, a condition that we had suspected in our patient. They found that these diverticula may persist, degenerate and disappear, or become detached in the form of epithelial nodules or cysts.

It is easy to understand how a cyst thus formed may occupy any position within the intestinal wall—submucous, intermuscular or subserous—or that it may occupy any position around the intestinal wall—mesenteric, antimesenteric or any intervening segment. A cyst on the mesenteric border in addition may lose its attachment to the intestine and occupy any position between the two layers of the mesentery.

DIAGNOSIS

In none of the cases reported has the diagnosis been made before operation. Waugh considered his patient to have a duodenal obstruction from an unknown abdominal tumor. Smith diagnosed his patient as having a congenital pyloric stenosis. Meyer's patient was thought to have pylorospasm, while we thought our patient had a choledochus cyst. All the patients had a palpable abdominal tumor except that of Meyer, and all the patients except ours were infants. The most important diagnostic points are the presence of a tumor in the region of the duodenum and the signs and symptoms of duodenal obstruction.

TREATMENT

Unless the duodenal cyst is in a favorable position, it is not likely that excision will be possible. Some form of drainage of the cyst will be necessary. In the two cases in the series in which attempts to correct the abnormality were undertaken, the cyst was drained externally. In one case the cyst refilled after two months and the child died following a second operation. In the other, the child died one week following operation.

We believe that, in those cases in which excision is not possible, the procedure of choice is permanent internal drainage of the cyst into the intestinal tract. This can be accomplished, as in our case, by an anastomosis between the cyst and the duodenal lumen. The drainage might be accomplished as well by an anastomosis between the cyst and the jejunum, provided a jejunojejunostomy is also performed. With the latter method of treatment the diverticulum resulting from the anastomosis would be less likely to become filled with intestinal contents. We thought that the three attacks which occurred in our patient following operation were caused by this complication, and we considered using the latter plan of treatment as outlined if the attacks had continued. We now feel that our patient, having been free from symptoms for fifteen months,⁹ will require no further surgical treatment, since the resulting duodenal diverticulum has been continually compressed by the normal duodenal musculature that surrounds it. The palpable mass has not been present since operation.

SUMMARY

1 A cyst of the duodenum was successfully treated by anastomosis with the intestinal tract.

2 Six cases of this rare condition have been collected from the literature, with a mortality of 100 per cent.

3 Three of the collected cases were treated surgically, two by external drainage.

4 The operation of choice seems to be permanent internal drainage into the intestinal tract.

5 There are two methods of accomplishing this, one having been used in the case here reported.

6 No case has been diagnosed before operation or autopsy. The symptoms are those of duodenal obstruction, with a palpable mass in the right upper part of the abdomen.

7 An embryonic diverticulum is the probable origin of the cyst.

8 Choledochus cysts probably have a similar origin from the persistence of diverticula that occur along the bile ducts during embryonic life.

Duke Hospital

⁹ A recent note from the patient's mother states that she has been entirely free from symptoms since November 1932.

APIOL POLYNEURITIS

REPORT OF A CASE

ROBERT DENISON, MD

HARRISBURG, PA

AND

J. C. YASKIN, MD

PHILADELPHIA

Prior to 1931, cases of polyneuritis caused by apiol had never been reported. The first reports came from Holland¹ and Yugoslavia.² Later cases were reported from Germany, France and other European countries.³ A careful perusal of the British and American literature did not reveal such reports.

REPORT OF CASE

Mrs. H. F., aged 25, admitted to the Harrisburg Hospital Aug. 10, 1934, with an irrelevant family and past history, complained of diarrhea, chills and fever, pain and swelling in the ankles and abdominal pain. July 20, 1934, she had attempted to terminate an early pregnancy by taking eighty-nine capsules of Savatin and fifty emmenagogue tablets over a period of two or three days. Savatin is a proprietary preparation, each capsule containing 2 minims (0.13 cc.) of apiol, 1 minim (0.06 cc.) of oil of tansy, and 1½ minims (0.1 cc.) of oil of savin. The following day a severe gastroenteritis developed with nausea, vomiting and generalized abdominal pain. Diarrhea followed on the next day and persisted until the middle of August. Chills, fever and sweats occurred later, with an extremely painful and swollen throat. On admission to the hospital, she was prostrated with a high fever and a relatively slow pulse. In the succeeding few days, an intractable tympanitis, severe epistaxis and a generalized rash resembling arsenical poisoning developed. At this time she complained of marked numbness in both hands and feet, which was followed by a pronounced hyperesthesia and the loss of power in the distal extremities. Masses suggesting condylomas appeared in the perineum, but studies with the dark field did not reveal spirochetes. The blood Wassermann reaction was negative. The urine revealed a few granular and hyaline casts, with a slight amount of albumin; the blood count showed a moderate leukopenia.

Read before the Philadelphia Neurological Society Oct. 26, 1934.

Examination of the urine and feces for arsenic was negative. The neurologic examination, made August 27, showed the following:

The mentality was quite clear. The patient was cooperative and answered questions slowly but accurately.

Examination of the cranial nerves was entirely negative in every detail. There was a slight weakness of the shoulder girdle muscles on both sides, perhaps more marked on the right side than on the left. There was no visible or palpable atrophy and there were no tremors. A very definite weakness of the biceps, triceps and supinators in both forearms was apparent. There was a pronounced weakness of the muscles of the right hand with little atrophy of the interossei. The power in the left hand was somewhat better, but there was much atrophy of the interossei in the muscles of the thenar eminence. The weakness in the hands was strikingly greater than in the forearms, and in the latter it was much greater than in the arms. The biceps and triceps reflexes were bilaterally abolished. There was tenderness all over the nerve trunks of the upper extremities, and this was most marked in the arms. There was a complete loss of sense of position and vibration up to the elbow on both sides. Touch was likewise diminished over the same area, while the tests for pain and temperature gave at times variable responses, especially in the most distal parts of the extremities. Pain and temperature were inaccurately preserved, while at other times the response was one of overaction.

The musculature of the trunk could not be tested satisfactorily as the patient was too weak to sit up. The abdominal reflexes could not be obtained.

There was no appreciable wasting nor were there tremors in any groups of the muscles in the lower extremities. She was unable to move the ankle joint in any direction, nor could she move any toes. She was barely able to flex the knees or the hips. The feet were supported by a pillow to prevent them from dropping. The knees and achilles jerks were entirely abolished. There was barely any response to plantar irritation. There was a very marked tenderness on pressure all over the nerve trunks, which was more pronounced in the calves of the legs and on pressure over the feet. The sense of vibration and position was entirely abolished in the feet, and the sense of vibration was entirely abolished as far as the knees. The response to pain and temperature was similar to that of the upper extremities, the hypalgesia and hypothermalgesia extending to about the upper third of the legs.

The neurologic examination was repeated October 24. At this time the patient was still paralyzed in both hands and feet, although there was a slight improvement in the motor power of the arms and legs. There was no appreciable improvement in the sensory status for vibration, deep position, tactile discrimination, pain, temperature and light touch. The biceps, triceps, knee jerks and ankle jerks were still abolished. Nerve trunk tenderness was still present but less marked. Electrical tests were not made.

COMMENT

The subject of polyneuritis following the use of apiol is well described by ter Braak and Carrillo,⁴ who collected thirty-seven cases from the literature and reported thirteen cases from Holland. According to these authors the average clinical course is as follows: Several days following the ingestion of the apiol preparation, variable gastro-intestinal symptoms appear, which subside in two or three days. A period of latency may then prevail, which may last from two to three weeks, with an average of seventeen days. Cramps appear suddenly in the muscles of the legs at the end of this period, and this is followed on the next day or two by paresthesia and weakness of the feet. About a week later paresthesias and weakness appear in the hands. The weakness then becomes progressively greater, while the pain and paresthesia diminish in intensity. About two weeks after the onset of the neuritis there is usually found considerable weakness

and some atrophy of the muscles of the hands and of the feet, while the more proximal muscles are affected but slightly, if at all. Pain and objective sensory changes are absent or are only slight. The biceps and triceps reflexes are preserved, the patellar reflexes are somewhat increased, while the achilles reflex is absent. There are usually found diminished responses to faradic stimulation and some other evidences of electrical reaction of degeneration. Fibrillary tremors are not observed. Spinal fluid studies and other laboratory investigations are negative.

The condition becomes stationary after two or three weeks, while the atrophy and electrical reactions of degeneration become more pronounced. It is not until a half year after the appearance of symptoms that improvement really begins, but eventually these patients make an almost complete recovery. Ter Braak and Carrillo stress the importance of the latent period, the purely motor character of the neuritis, and the predilection for the symmetrical and distal muscle groups.

Our case differs somewhat from the European variety. At the outset there were severe gastro-intestinal symptoms and marked skin and mucous membrane reactions, which are not mentioned in the literature. The duration of the latent period was twenty-one days. The neurologic involvement was somewhat more extensive than in the cases reported in the European literature, appearing, however, pre-eminently motor, distal and symmetrical. The fact that our patient ingested an exceedingly large dose of the drug in a short period of time may help to account for the severity of the symptoms.

All the cases reported would tend to show that the process is limited to the peripheral nerves and that there is no involvement of the central nervous system. The cause of this neuritis is not due to apiol⁵ but to triorthocresyl phosphate, which is contained in the abortifacient Apioi, which is an extract of parsley, is in itself nontoxic. The fact that triorthocresyl phosphate is capable of producing neuritis has been known for a long time. In 1899 Lorot⁶ described a case of polyneuritis following the use of creosote phosphate in the treatment of pulmonary tuberculosis. Similar cases were reported by Loewenfeld,⁷ Wertheim Salomonson,⁸ Huet,⁹ Sanz¹⁰ and Bertolani.¹¹ Lastly, the jamaica ginger paralysis in the United States in 1930¹² also was traced to triorthocresyl phosphate. It is interesting to note that the clinical course of the cases treated for pulmonary tuberculosis, the cases of jamaica ginger paralysis¹³ and those due to the ingestion of apiol show

most the same characteristics. The cases of jamaica ginger paralysis show more extensive weakness, more intense and widespread atrophy, and more markedly affected tendon reflexes. Our case resembled strikingly the jamaica ginger type of paralysis.

The pathogenesis of triorthoresyl neuritis would appear to depend on the selective action of the toxic substance on myelin sheaths of the peripheral nerves with secondary degeneration of the axis cylinders (perivascular neuritis). This was shown experimentally especially on chickens by ter Braak and Carrillo⁴ and by Smith and Lillie¹⁴ and in the clinicopathologic investigations in jamaica ginger paralysis by Jeter,¹⁵ Hurley¹⁶ and Goodale and Humphreys.¹⁷ In addition to the peripheral nerves of the extremities, triorthoresyl is reported to have caused retrobulbar neuritis.¹⁸

Clinical Notes, Suggestions and New Instruments

A SIMPLIFIED APPARATUS FOR THE APPLICATION OF SUCTION AND PRESSURE TO THE LOWER EXTREMITIES IN PERIPHERAL VASCULAR DISEASE

JAMES J. SHORT, M.D., NEW YORK
Assistant Professor of Medicine, New York Post-Graduate Medical School of Columbia University

Vascular disease of the lower extremities, sufficient to cause symptoms of impaired circulation, is in the majority of cases of the arteriosclerotic type, such cases outnumber many times those presenting vascular spasm. Whereas symptoms due to vascular spasm can often be promptly alleviated by measures undertaken to relax the spasm, those having organic occlusion respond little to such measures, and results are usually discouraging.

One selected small group of arteriosclerotic cases presenting such changes as intermittent claudication, trophic lesions and other physical signs of organic occlusion were systematically treated over varying intervals of from three to six months by such measures as hyperthermia induced by the intravenous injection of typhoid vaccine, by Buerger's exercises, alternate hot and cold applications, the systematic use of a tourniquet to induce passive hyperemia, the hypodermic injection of acetylcholine, the intravenous injection of calcium gluconate and the oral administration of iodides, sodium salicylate, calcium lactate and theobromine. Differentiation between spasm and organic occlusion was made on the basis of history, general physical examination and vasodilator response to nerve block or the application of heat.¹ It was my experience that the patients in this group were mostly unimproved at the end of several months of systematic treatment.

The work of Landis and Gibbon² on the effects of alternate suction and pressure on blood flow in the lower extremities seemed to indicate that this method had greater promise of definite benefits than any method heretofore in use. An apparatus was therefore constructed, based on their suggestions

² Landis, E. M. and Gibbon, J. H. Jr. The Effects of Alternate Suction and Pressure on Blood Flow to the Lower Extremities. J. Clin. Investigation 12: 925 (Sept.) 1933.

Many details are shown in the accompanying illustrations. A rotary pump with a capacity of 10 cubic feet per minute, driven by an electric motor of one-fourth horse power, is connected with a chamber of sheet metal 76 cm long, 28 cm square at the open end and 28 cm by 34 cm at the closed end. To the margin of a round opening 15 cm in diameter, through semiflexible rubber of 1 inch thickness used to close the smaller end of the chamber, is vulcanized a pneumatic rubber cuff similar to that

Fig. 1—Appearance of simplified apparatus for application of suction and pressure to the lower extremities in peripheral vascular disease.

used with sphygmomanometers. This is 6 inches in length and tapers to approximate the thigh. Its outer wall is fairly heavy, its inner wall lighter and more flexible. Air is introduced into the cuff through a pressure bulb and is regulated so as to exert the minimal pressure necessary to seal the juncture with the thigh. This new design has obviated previous difficulties with leaks due chiefly to variation in the size of thighs.

Fig. 2—Diagram of apparatus. EM, electromagnets; R, regulating valves; G, mercury gage; B, box; I₁, inlet to box; I₂, outlet; P, pressure pipe; S, suction; C, compressor; T, timer for EM; M, motor; RC, rubber cuff; W, Wiew glass.

Following Landis's suggestions as to optimal periods a negative pressure is produced within the chamber for twenty-five seconds followed by a positive pressure for five seconds. Thus far pressures of from 110 to 120 mm negative and from 80 to 110 positive have been used. A rapid reversal of air current is obtained through the use of valves operated by electromagnets as noted in figure 2. The electromagnets are activated from a switch on a cam driven through a reducing gear from the

pump. The motor and pump operate continuously throughout the treatment, the pressure within the apparatus being maintained at the desired height through the use of relief valves which in turn can be regulated to produce any pressure within the apparatus that may be desired.

The design of the apparatus differs mechanically from that of Landis and Gibbon in several respects: (a) Relief valves are used, which can be regulated to produce any pressures desired, (b) the pump operates continuously, (c) the use of adhesive plaster with the cuff is eliminated and a regulated pneumatic pressure is applied, (d) alternation from negative to positive pressure is produced directly from a single motor by means of electromagnets operating a valve system rather than by a second motor to rotate the four-way valve as described by them, (e) duration of the periods of negative and positive pressures can be readily changed by adjusting the cam.

Results of treatment thus far have been encouraging. Further experience is necessary, however, to evaluate conclusively this method of therapy.

A LABORATORY TEST OF "HOXIN" AS A CLAIMED CANCER CURE

C. C. LITTLE, SCD, AND A. M. CLOUDMAN, PH.D.
BAR HARBOR, MAINE

One of the difficulties in connection with various claims that substances which are cures for cancer have been discovered is to obtain an adequate experimental test of these substances on cancer in laboratory animals.

This brief communication records such tests of a substance called "Hoxin," advanced by Mr. Harry Hoxey of Philadelphia as a cure for cancer. This substance is used for treatment in two forms: (a) as a solution administered orally for internal cancer, (b) as a powder placed directly in contact with external cancer.

The laboratory material used consisted of mice inoculated with a malignant tumor, No. 15091a, reported on by Cloudman.¹

INTERNAL TREATMENT

EXPERIMENT 1—Thirty mice were inoculated subcutaneously with tumor 15091a, Nov. 13, 1934. Beginning on the same day they were given as the sole liquid element in their diet a solution of "Hoxin" designated as of "X" strength. On the sixth day (November 18) this strength was doubled to "2X." These mice all died of cancer.

Controls consisted of twenty mice similarly inoculated but whose liquid diet was tap water. These mice also all died of cancer.

EXPERIMENT 2—Nov. 30, 1934, fifteen mice were placed on a diet the liquid element of which was a "full strength" (8X) solution of "Hoxin." On the following day they were inoculated with tumor 15091a. The tumor grew progressively in all of them. They all showed healthy growing tumors at death. These animals were weighed before the treatment began. Under it they lost weight rapidly and showed generally a very poor physiologic response.

Controls consisted of five mice whose liquid diet was tap water. Otherwise treatment was the same. These mice lost no weight but also died with actively growing tumors present.

EXPERIMENT 3—Nine mice were kept for three weeks on a diet the sole liquid element of which was a 6X solution of "Hoxin." They were then inoculated with tumor 15091a. They all grew the tumor rapidly and died of it.

The obvious conclusion is that internal treatment with "Hoxin" has no preventive or curative effect on mice inoculated with tumor 15091a.

EXTERNAL TREATMENT

EXPERIMENT 4—Ten mice were inoculated with tumor 15091a, Nov. 13, 1934. November 21 they showed palpable masses. Under pentobarbital sodium the skin over the tumor was cut and a small incision was made in the tumor mass. On this

incision an amount of powder "sufficient to cure a human epithelioma" was placed. These mice all died of cancer. A violent reaction to the powder was obtained. Hard lumps, apparently necrotic and inflammatory, were observed near and around the tumor, and selective elimination of tumor cells was not apparent.

Ten controls treated in exactly the same way except for the powder showed no such reaction but died of cancer.

EXPERIMENT 5—Ten mice were inoculated with tumor 15091a, November 13 and on November 22 had their tumor masses treated as in experiment 4. At death they all had healthy growing tumors.

EXPERIMENT 6—Ten mice were inoculated with tumor 15091a, Nov. 13, 1934, and (without pentobarbital sodium) were treated with powder, November 23. At death, all showed healthy growing tumors. In several of these mice, marked corrosion and destruction of normal tissue was noted. In one (mouse 6) the destruction of normal tissue had extended through the walls of the pericardial cavity and peritoneum and had affected the surface of the liver, causing adhesions.

No such destruction of normal tissue and no inflammation or necrosis were noted in the controls.

The conclusion is that direct application of powdered "Hoxin" does not "cure" mice inoculated with tumor 15091a.

In addition, there is no sign of selective action for tumor tissue, and actual destruction of normal tissue may be extensive.

Special Article

GLANDULAR PHYSIOLOGY AND THERAPY

THE THERAPEUTIC USE OF ESTRO- GENIC SUBSTANCES

EMIL NOVAK, M.D.

BALTIMORE

NOTE—This article and the articles in the previous issues of THE JOURNAL are part of a series published under the auspices of the Council on Pharmacy and Chemistry. Other articles will appear in succeeding issues. When completed the series will be published in book form.—Ed.

Estrogenic substances are those which produce estrus directly. There are other substances, notably the gonadotropic principles of the anterior pituitary lobe, that can produce estrus indirectly through their activating effect on the ovarian follicles. The present article deals with the therapeutic applications of estrogenic substance itself. This name is chosen as a generic term in preference to the others commonly employed, to avoid possibly misleading implications as to chemical constitution, source or function and to emphasize that such principles produce estrus, and not menstruation, which is a very different thing.

It would be out of the question to attempt a collective review of the vast literature of the subject within the limits of a short paper, so that this article is offered rather as a summary of conclusions and impressions gained from a fairly extensive survey of the literature and a reasonably large clinical experience. For an excellent summary of the literature on estrogenic substances, the reader may be referred to the special article published by the Council on Pharmacy and Chemistry.¹

In spite of the remarkable advances made in reproductive physiology, there is still much confusion on many points, even among scientific investigators, so that

From the Roscoe B. Jackson Memorial Laboratory,
1. Cloudman, A. M. *Am. J. Cancer* 10: 568-630 (May) 1932.

1. Estrogenic Substances. Theelin report of the Council on Pharmacy and Chemistry. *J. A. M. A.* 100: 1331-1338 (April 29) 1933.

it is not surprising that the therapeutic application of these new advances is anything but clearly defined. Every one feels that gynecologic organotherapy is, on the whole, extremely disappointing, and yet the feeling is universal that it is in this direction that one must look for improvement in methods of treating the functional gynecologic disorders. Adding to this the great frequency of these disorders, and the fact that no other satisfactory treatment is known, it becomes easy to understand why the harassed clinician will continue to employ endocrine therapy in spite of its questionable value for many indications. To paraphrase a popular automobile slogan, When better methods are found, the clinician will use them.

In the meantime it behooves the clinician to make his organotherapy as rational as possible, and this can be done only by familiarizing himself with at least the elements of reproductive physiology and endocrinology. It seems unavoidable to include in this paper a discussion of some forms of treatment which are admittedly unsatisfactory and inadequate but which the clinician, without loss of dignity and self respect, will often use for the simple reason that they are for the present the best available to him.

PHYSIOLOGIC BASIS FOR ESTROGENIC THERAPY

While the physiology of estrogenic substance is considered in other articles of this series it seems advisable to set forth, in epitomizing fashion, the major premises on which this discussion of therapeutic applications is based.

1 Estrogenic substance is an active principle of the growing ovarian follicle, although found in many other body tissues and fluids, such as the placenta, the amniotic fluid, and the urine of pregnant women.

2 The physiologic effect of estrogenic substance on the endometrium is to produce growth and hyperemia but not secretory activity.

3 The corpus luteum formed after rupture of the follicle (usually about the middle of the intermenstrual interval) continues, in the human being at least, to secrete estrogenic substance, but in addition produces another hormone, "progesterin," to which is due the secretory activity of the endometrial gland epithelium so characteristic of the premenstrual or premenstratory phase of the cycle.

4 The actual bleeding of menstruation, according to the weight of present evidence, is brought about by an abrupt withdrawal of estrogenic substance, bringing about partial destruction and desquamation of the endometrium, with resulting hemorrhage.

5 Certain nonmenstrual types of bleeding may be produced by similar drops in the blood level of estrogenic substance.

6 Both follicle ripening and the secretion of estrogenic substance, on the one hand, and luteinization and the production of progesterin, on the other, are due to the influence of the gonadotropic hormones of the anterior hypophysis.

7 There is practical unanimity among investigators that estrogenic substance is not a stimulant of ovarian activity, the evidence indicates that sufficiently large or prolonged dosage inhibits ovarian activity, because of the depressing effect of estrogenic substance on the secretion of the anterior pituitary gonadotropic hormones.

8 While there is some difference of opinion on this point, the work of the great majority of the best investigators indicates that estrogenic substance is responsible for the normal rhythmic contractility of the uterine musculature and that progesterin is an inhibitor of this property.

PREPARATIONS AVAILABLE

It seems impossible to avoid the use of trade names in the discussion of the estrogenic substances available for clinical use. Indeed, unless this is done, this article might mean very little to the average reader. The better manufacturers appear to be making an honest effort to supply the profession with substances of genuine estrogenic potency, and their laboratories have shown a commendable willingness to cooperate both with clinicians and with laboratory workers in the investigation of the many problems of gynecologic endocrinology. That their ultimate purpose is commercial need not necessarily be considered an objection, though it naturally explains the uncritical attitude sometimes shown in their interpretation of clinical results.

None of the estrogenic preparations have as yet been accepted by the Council on Pharmacy and Chemistry, although their use in clinical practice is widespread. For the present, the safest course for the practitioner is to employ only preparations made by manufacturers of recognized standing. Because most of the estrogenic material employed in this country is made by two large American manufacturers and one German firm, it seems worth while to enumerate the preparations made by these, as they are representative of general types. No attempt can be made to pass judgment on the comparative potency or therapeutic efficacy of these preparations, nor is there any implication that any of them is superior to products made by other American or foreign firms. On the other hand, the notorious general unreliability of certain manufacturers of organ extracts would seem a safe indication as to the probable unreliability of the estrogenic substances which they manufacture.

Preparations for Oral Administration—Of the older forms of whole ovarian substance, ovarian residue and corpus luteum extracts, little need be said. They are now commonly accepted as being inert or almost inert, containing little or none of the active hormones, with the further disadvantage that even this little is largely nullified by the digestive juices.² There would seem to be no reason for their employment at the present day, when preparations of demonstrated laboratory potency are readily available. The following preparations of the estrogenic substances are the ones most widely employed in this country.

Theelol (P. D. & Co.), a trihydroxy derivative of theelin, marketed in capsules of 50 rat units each.

Amnotin (Squibb) in gelatin capsules each containing 1,000 international units.

Progvnon (Schering), in tablets of 45 rat units. This product is claimed to be a placental extract, in which the estrogenic substance is not reduced to the crystalline state, it is said to contain, in addition, certain placental lipoids.

Preparations for Hypodermic Administration—These are as follows:

Theelin (P. D. & Co.), an aqueous solution of the crystalline theelin of Doisy, in 1 cc. ampules of 167 international units.

Theelin in oil (P. D. & Co.) in 1 cc. ampules with a potency of 1,000 international units.

Ammiotin (Squibb), in 1 cc ampules, each containing either 2,000 or 8,000 international units in corn oil

Progynon (Schering) in 1 cc ampules of 25 rat units of estrogenic substance in aqueous solution

Progynon B (Schering), in 1 cc ampules, of 10,000 or 50,000 international units of hydroxyestrin benzoate in sesame oil

Unit of Dosage—The unit of dosage commonly employed in this country is the Allen-Doisy rat unit, defined as the quantity of active principle, divided and given in three injections at four hour intervals, necessary to induce estrus within three days, as judged by the presence of cornified cells in vaginal smears, in ovariectomized sexually mature rats of a standard weight (140 ± 20 Gm). The international unit, now coming into use, is that dosage necessary to produce an effect, under identical conditions, equal to that of 0.1 microgram (0.0000001 Gm) of a standard preparation of crystalline theelin. According to the report issued by the League of Nations^{2a} the international unit is about one-third the Allen-Doisy rat unit^{2b}

ROUTES OF ADMINISTRATION

From the point of view of the patient, the most convenient plan of estrogenic therapy is undoubtedly the oral. It should be remembered, however, that the digestive juices apparently have a destructive effect on estrogenic substance and that approximately five times the effective hypodermic dosage must be used when the substance is administered orally. As estrogenic products are quite expensive, the hypodermic route will often be chosen, especially in view of the greater precision as to the dosage absorbed by the patient.

For long continued use, and especially when smaller amounts are necessary, the oral route possesses many advantages. This is especially true in the treatment of the menopausal symptoms.

As the estrogenic substances are absorbed through the vaginal mucous membrane, they are sometimes administered by vaginal suppositories. There is always much uncertainty, however, as to the amount actually absorbed, especially as the suppositories are not infrequently lost from the vagina. Because of this and because of the disagreeableness of this method to many women, it has not achieved any great vogue. Nor has the nasal spray method, suggested by Pratt and Smeltzer.³ Furthermore, with the increasing development of oral therapy, there would seem to be no advantage in either the vaginal or the nasal method.

INDICATIONS

Amenorrhea—While the treatment of amenorrhea by estrogenic substances is notoriously unsatisfactory, it is in this condition, perhaps more often than any other, that they are employed, so that a fairly full discussion of this subject may not be omitted from this paper. The limitations of estrogenic substance in the relief of amenorrhea are at once apparent if one will bear in mind that although such products are certainly capable

of producing estrus in animals, the latter phenomenon is very different from menstruation in women. No amount of estrogenic substance can produce in the endometrium the sequence of histologic changes characterizing the menstrual cycle, for always the secretory phenomena dependent on the presence of progesterin are lacking. It has been suggested that in some cases the giving of large amounts of estrogenic substance may build up the endometrium so that in spite of existing deficiency of the corpus luteum hormone (progesterin) the histologic cycle, with the culminating premenstrual secretory phase, may be completed. There is, however, no scientific evidence for this, and clinical results make it questionable.

The second important shortcoming in estrogenic therapy of amenorrhea is the fact, already emphasized, that there is no activating effect on the ovary itself, so that such therapy is purely substitutional and applies to one particular cycle, with no reason to expect reestablishment of the regular menstrual rhythm.⁴ Here again it has been stated by some that theelin may stimulate the anterior hypophysis and thus activate the ovarian function, but the weight of available evidence is exactly to the contrary.

In the treatment of amenorrhea, it must be remembered that this disorder may be a symptom of many possible underlying conditions, usually constitutional, occasionally local. A very complete investigation is necessary before one can arrive even at an intelligent surmise as to the mechanism involved. The correction of a causative constitutional factor, when this can be found, makes unnecessary any direct organotherapy of the amenorrhea. In other cases, notably those of thyroid origin, the administration of thyroid may be all that is necessary. Speaking generally, the primary form of amenorrhea is much more intractable to treatment than is the secondary.

Aside from the hypothyroid group, the two types in which direct ovarian organotherapy is most often employed are the hypogonadal and hypopituitary, the assumption being that in the first the secretory defect involves the ovaries, while in the second it is the activating function of the anterior lobe which is at fault. In some cases clinical evidence makes such diagnoses plausible, in others blood and urine hormone studies seem to justify them.

With reference to the wisdom of qualitative and quantitative hormone studies when practicable there would seem to be no doubt, although as yet they have added very little to therapeutic success. The value of a single blood hormone determination is very doubtful, and the rather large amounts of blood necessary for the tests make their frequent repetition impracticable as Neumann⁵ and others have emphasized. The interpretation of the results of urine hormone study is often difficult, because of uncertainties as to the factors governing the renal excretion of the hormones and also ignorance of whether the excreted hormones represent a real excess or whether they have already fulfilled a function in the body. There is no doubt that the excellent studies now being prosecuted on blood and urine hormone in many clinics will yield valuable results, but those thus far obtained would not seem to justify

^{2a} League of Nations. Conference on the Standardisation of Sex Hormones. Quarterly Bulletin of the Health Organisation. Special Number, January 1935, p. 121.

^{2b} In comparing the potencies of the various commercial preparations and in calculating dosage it should be kept in mind that the different firms employ different ratios for the comparative potencies of the rat unit and international unit. Thus Parke Davis and Company considers the rat unit to be about 3.3 times as large as the international unit; the Schering Corporation indicates that one rat unit is equivalent to five international units, while E. R. Squibb and Sons considers the rat unit to be eight times the international unit. For a discussion of assay methods the reader is referred to the report of the Council on Pharmacy and Chemistry¹ and to the report of the League of Nations.^{2a}—Ed.

³ Pratt, J. P. and Smeltzer, N. Endocrinology, 13: 320-326 (July-Aug.) 1929.

⁴ Novak, Emil. Brit. M. J. 2: 553-557 (Sept. 23) 1933. Am. J. Obst. & Gynec. 24: 319-329 (Sept.) 1932.

⁵ Neumann, H. O. Zentralbl. f. Gynak., 56: 391-394 (Feb. 13) 1932.

insistence on such studies in all cases encountered by the clinicians for whom this article is chiefly intended. In the recent paper by Frank and his associates⁶ "emphasis is placed on the accurate size up of the individual studied and on other laboratory aids which help in the recognition and evaluation of congenital and acquired endocrine stigmas." This paper may be referred to as an excellent summary of the hormoneology of the menstrual disorders.

So far the comments on the ovarian therapy of amenorrhea have been entirely adverse, and perhaps not a great deal would be lost if the discussion stopped at this point. And yet the harassed clinician is always insistent on some plan of procedure in the management of amenorrhea, especially as the amenorrheic patient is herself so worried about her condition and so anxious for its correction. This is particularly true because of the prevalent belief of the public that menstruation is essential to health and well being and that absence of the function, with its supposed retention of harmful substances in the system, may bring about serious results.

After a thorough study of the patient in an effort to determine the cause of the symptom one of the greatest services the physician can render is to impress on the patient the essential harmlessness of the amenorrhea per se and to explain to her in the simplest possible fashion the real meaning of menstruation, emphasizing especially that its purpose is not to rid the body of harmful substances. In many patients, especially those approaching the middle period of life or those in whom sterility is not a complicating problem, nothing more is necessary.

When, for one reason or another, treatment is called for, there can be no objection to efforts at ovarian therapy, so long as one appreciates its limitations. The administration of the estrogenic principles alone may at times be followed by bleeding, though a closer simulation of the normal hormone sequence would be obtainable by following the estrogenic substance with the corpus luteum hormone. The latter is not yet available commercially, though in a number of reported cases a typical menstrual period, with its typical sequence of proliferative and secretory changes in the endometrium, was produced by this combined therapy in women who had been castrated a number of years previously.⁷ Enormous dosages, however, were necessary. In Kaufmann's case, for example, 320,000 mouse units (about 65,000 rat units) of the estrogenic principle, followed by 90 rabbit units of progesterin, was required, while in the other reported observations similarly huge doses were found necessary.

These studies would indicate that the usual therapeutic doses of estrogenic substance are ridiculously small, for ordinarily not more than 100 units daily for perhaps from six to twelve days (by the hypodermic route) has been employed. Even this dosage is expensive for the patient, while amounts of estrogenic substance that might fairly be considered adequate would be prohibitive to all except a few patients. One of the existing problems of American manufacturers is to produce these estrogenic principles at a very much lower cost, perhaps comparable to their low cost in

Germany, and it is encouraging to learn that there is a prospect of improvement along this line in the near future.

Another difficulty lies in the present unavailability of progesterin, which is found only in corpora lutea, a large amount of which is required to produce a small amount of the active principle. For the present the nearest approach to progesterin for clinical purposes—though admittedly an unsatisfactory one—is the so called anterior pituitary-like gonadotropic hormone of the urine of pregnant women (sometimes designated prolan). This substance has been discussed more fully in another article of this series. Suffice it to say here that some clinicians advocate the administration of this substance immediately following the completion of the course of estrogenic substance already suggested, an average dosage by the intramuscular route being 150 or 200 rat units daily for five or six injections. Others administer the two substances synchronously. As the anterior hypophysis is unquestionably the activator of the ovary, the hope for the intelligent treatment of amenorrhea is in the development of a really gonadotropic preparation for clinical use. The evidence indicates that the present day anterior pituitary-like preparations do not fill the bill.

Many clinicians prefer to use estrogenic substance by the oral route, though it should be remembered that the effective dose by mouth is about five times the hypodermic dose. If the cost of production of the estrogenic principles can be very materially lessened, the oral route will probably become the popular one. For amenorrhea, however, in which the object should be to give the patient the benefit of the largest dose possible at the lowest possible cost, the hypodermic route has definite advantages in spite of certain rather obvious objections. A combination of the oral and hypodermic methods is often employed.

This general plan of treatment is offered very unenthusiastically, because it will usually be unsuccessful. There are, of course, a considerable number of reports in the literature as to the success of ovarian therapy, but the dispassionate reader will immediately recognize that most of these are highly uncritical. In many reports, for example, the statement is made that estrogenic treatment was followed by bleeding, with no comment on whether there was periodic recurrence of the bleeding. In the minority of cases in which such recurrence is reported, it is difficult to explain this on the basis of any known physiologic facts, especially as the ovary itself is not stimulated by the estrogenic substance.

To say that it is impossible for estrogenic substance in any dosage ever to reestablish menstruation would be an extreme statement, in view of ignorance as to the hormone mechanisms involved. Such an occurrence, however, is so rare that the factor of coincidence cannot be eliminated, and the "post hoc propter hoc" sequence cannot be assumed. If these remarks appear unduly pessimistic, I can say only that I know of no gynecologist of standing who is not unenthusiastic about the treatment of amenorrhea by estrogenic substances. On the other hand, I know of few who do not often resort to organotherapy for amenorrhea because they know of no treatment that offers any more prospect of success.

Frank and his associates⁶ cite a number of cases in which spontaneous reestablishment of the menstrual

6 Frank, R. T., Goldberger, M. A. and Spielman, Frank. Present Endocrine Diagnosis and Therapy. *J. A. M. A.* 103:393-402 (Aug. 11) 1934.

7 Claiberg, C. Zentralbl. f. Gynak. 57:1461-1468 (June 24) 1933. Kaufmann, C. *Ibid.* 57:42-46 (Jan. 7) 1933.

function occurred, suggesting that many supposedly successful therapeutic results are explainable on this basis. While this is unquestionably true, my observation has been that in the usual type of endocrinopathic amenorrhea of long duration spontaneous reestablishment of the function is uncommon, so that the unwillingness of both physician and clinician to hang to this hope is understandable and justifiable. As with certain types of almost hopeless cancer, he will do the best he can with the admittedly unsatisfactory methods available to him. If a sly dig is permissible, reference may be made to the "Queries and Minor Notes" columns of the erudite JOURNAL, in which so frequently advice is sought as to the treatment of endocrinopathic amenorrhea. I do not recall an instance in which the answer omitted suggestions as to organotherapy, though always with a fair statement of its limitations and inadequacy.

Functional Uterine Bleeding—While the estrogenic substances have been used by some gynecologists in the treatment of functional bleedings, and while this plan is recommended in the literature of some manufacturers, it does not seem logical. In general, this menstrual disorder is due to a relative increase in estrogenic substance and a corresponding absence of progesterin, though it is true that the actual bleeding may well be due to periodic drops in follicular secretion, because of the reciprocal effects of the latter on the anterior hypophysis. However, it would scarcely seem possible to ward off the drop indefinitely by supplying estrogenic substance artificially. Furthermore, a much more frequently successful plan in the management of such cases is available in the administration of the anterior pituitary-like gonadotropic hormones derived from the urine of pregnant women (antuitrin S or follutein), as suggested by Novak and Hurd.⁸ This subject is considered more fully in another article of this series.

Menopausal Vasomotor Symptoms—This indication for the employment of estrogenic substances appears to have achieved much more widespread acceptance than any other. It should, first of all, be emphasized that the majority of menopausal women need no organotherapy whatever, for either the symptoms are very slight or they are controllable by such simple measures as reassurance, insistence on the avoidance of physical or mental stress or worry, and perhaps the use of such simple nerve sedatives as the bromides. In a minority of cases, however, and not infrequently also in the artificial menopause, produced by radium therapy or operation, the symptoms may be so distressing as to call for efforts at relief.

While such plans of treatment as hypophyseal irradiation are advocated by some, organotherapy is certainly the first thought of almost all practitioners. There is a considerable measure of rationale in the plan. For example, it has been shown by hormone studies that in at least some phases of the menopause a diminution in secretion of estrogenic substance occurs (Zondek⁹), and it is in this phase that the characteristic vasomotor symptoms are apparently most pronounced. Again, the removal of granulosa cell ovarian tumors which produce large amounts of estrogenic factor and only this substance, is apt to be followed by characteristic menopausal

symptoms, even in old women who had already experienced a normal menopause many years previously (Novak, Schulze, Dworzak).

It is scarcely necessary to stress the difficulty in the interpretation of subjective symptoms or of eliminating the ever-possible psychic factor. A measure of objective evidence is available, however, in the number of the vasomotor flushes that constitute the most characteristic menopausal symptom, and there would seem little doubt that therapy with estrogenic substance is of real, though very variable and inconstant value for this group of symptoms. It is only fair to state, however, that some excellent gynecologists have little confidence in any endocrine treatment of the menopausal symptoms. I do not share the extreme pessimism expressed in this regard in the recent paper of Frank, Goldberger and Spielman.¹⁰

Many plans of carrying out the treatment have been employed. As the required dosage is apparently not large, the oral route is more frequently applicable here than with certain other indications, though in severe cases the hypodermic method is probably more efficacious. Severinghaus¹⁰ has recently made a study of the comparative efficacy of the various routes of administration of estrogenic substance and finds both the hypodermic and the oral methods successful, although the latter requires five times the dosage of the former.

When the menopausal symptoms are not very severe, one of the oral preparations (theelol, amniotin oral, progynon) will probably be the method of choice, the dosage averaging from 100 to 200 rat units a day. When the vasomotor flushes come thick and fast, more striking results are obtained from the daily injection of 50 rat units of one of the aqueous or oily solutions.^{2b} Such medication is not necessarily expensive to the patient, because the organotherapy need usually be resorted to only from time to time, when the severity of the symptoms seems to necessitate it.

Gonorrheal Vaginitis in Children—An interesting therapeutic application of biologic knowledge has recently been suggested in the management of this, one of the bugbears of gynecologic practice. It has long been known that estrogenic substance is capable of producing very pronounced proliferation of the vaginal epithelium in immature laboratory animals, with desquamation after discontinuance of the injections. In view of this fact, the suggestion was made by Lewis¹¹ that the estrogenic preparations might prove of value in the treatment of gonorrheal vaginitis in children, and this was apparently borne out in the cases in which the method was tried. Since then, favorable results have been reported by Brown,¹² Huberman and Israeloff,¹³ and others, although the method is too new to warrant sharply defined opinions.

That proliferation of the vaginal mucosa can be produced in children by this method permits of no doubt, the two chief questions now being (1) the rapidity and permanence with which the gonococcus can be made to disappear, and (2) the possibility of any injurious by-effects. With reference to the latter, the objection

⁹ Zondek Bernhard. Die Hormone des Ovariums und des Hypophysenvorderlappens. Berlin Julius Springer 1931.

has been raised that the injection of estrogenic substance might produce harmful effects on the child's ovary, through the medium of the anterior hypophysis, though this seems unlikely with the recommended dosage. Experimental studies have shown a rather rapid restitution of ovarian function in animals even when large and prolonged dosage had brought about extreme ovarian impairment (Hisaw et al.)

The fear that the pelvic hyperemia produced by estrogenic substance may predispose to uterine and tubal pelvic extension of the vaginal infection is probably more apparent than real, though only time and the continued employment of this plan of treatment can decide this point. Enlargement of the breasts may occasionally be noted during the treatment, but this is transitory. So far as I know, vaginal bleeding has not been observed, though theoretically one might expect it to occur occasionally after the cessation of the injections.

The great advantage claimed for the method is the rapid disappearance of the infecting organisms, so resistant to all other known methods of treatment. Of his seven patients, Brown¹² states that four showed negative smears at the end of ten days, while six were negative at the end of twenty days and all seven at the end of thirty days. The method is now being tried out on a large scale in several clinics and it should not be long before the results of such studies will permit of a more accurate evaluation than is now possible.

For the present it can be said that the method is one of great promise, that its employment in the treatment of the gonorrheal vaginitis of children is proper, but that it should be combined with careful bacteriologic study, in order to check on the rapidity of disappearance of gonococci and especially to determine whether or not the patient may escape the relapses so characteristic of this disease.

The dosage recommended by Lewis is 50 rat units hypodermically each day the average total amount administered being 2100 units. The duration of treatment in his cases averaged twenty-one days. Local treatment is not used.

Hemophilia—In 1931, and in papers since then, Birch¹⁴ has advocated the use of ovarian extracts in the treatment of hemophilia, stating that estrogenic substance was found to be absent from the urine of a number of hemophiliac patients though present in the urine of normal males. The beneficial results of the treatment, as reported by her, seemed rather surprising in that they were often obtained from the oral administration of ovarian preparations commonly believed to be almost inert. Theelin, an admittedly potent preparation, she found to be "not so good as whole ovary." A number of other authors reported similarly good results from the treatment.

A recent thorough study of the question by Brem and Leopold,¹⁵ however, seems to discredit Birch's observations quite completely. They were not able to demonstrate the presence of the estrogenic hormone in the urine of normal males, and they urge that, if this substance really holds hemophilia in abeyance, it should be present in the urine of all normal males. Furthermore, in a case of hemophilia that they studied, they

failed to observe any reduction in the coagulation time of the blood or any hemostatic effect from the use of an estrogenic substance of known potency. They look on the symptomatic treatment of hemophilia and the employment of blood transfusions as still the method of choice in the treatment of this disease.

Other Indications—Dysmenorrhea has been treated with the estrogenic principles, either empirically or on the basis of Kennedy's¹⁶ view that the symptom is due to degenerative changes in Frankenhauser's ganglion as a result of deficiency of estrogenic substance. This work, however, is unsupported by any confirmatory evidence, and there is, on the other hand, much evidence to indicate that this factor is the normal stimulant of uterine contractility, so that its use in dysmenorrhea appears irrational. When there is an associated hypoplasia of the uterus, the use of estrogenic substances, because of their effects on the blood supply and development of the uterus, would seem proper. When such treatment is used, the substances should be given after menstruation and in the midinterval period rather than just before the expected date of a period.

Sterility is often an accompaniment of endocrinopathic amenorrhea, and its endocrine treatment is on an even more unsatisfactory scientific basis than that of the latter, so that it seems scarcely worth while to theorize on this subject in this short paper. Though it is possible that deficiency of follicular secretion may occasionally be the cause, treatment on this basis is in the nature of a "shot in the dark" and will rarely be successful. Even if pregnancy occurs, it is difficult to eliminate the factor of chance. The kraurosis of the vulva occasionally seen in women at the menopause is looked on as probably due to withdrawal of the follicular hormone, and ovarian therapy is resorted to by most gynecologists, but the results are rarely striking.

The condition of painful breasts or "mastoplasia" is said by Cutler¹⁷ to be favorably influenced by the oral administration of ovarian residue, while Whitehouse¹⁸ believes that the hypodermic use of estrogenic substance is to be preferred. Aside from uncertainty as to the rationale of these methods, it is hard to believe that any worthwhile benefit could come from the oral administration of ovarian residue, generally believed to be practically inert. That the ovarian hormones are responsible for the development of certain benign conditions of the breast seems unquestionable, in the light of such recent investigations as those of Lewis, Geschickter and Hartman, but excess of estrogenic substance appears to be most often the responsible factor, so that such therapy would seem illogical.

The Concept of "Antihormones"—The recent suggestion of Collip and his co-workers that the continued administration of various hormones excites the formation of antihormones so that there is a diminution or loss of the characteristic response to these hormones, is one which must arrest the attention of everyone interested in endocrinology. In spite of the high standing of these investigators, it is only fair to state that judgment must be reserved until their results are con-

firmed Hisaw, another excellent investigator, in some as yet unpublished studies (personal communication), has observed somewhat similar results, but his investigations indicate that these, species-specific reactions are to be interpreted as antibody effects rather than as anti-hormone reactions¹⁹

SUMMARY

Estrogenic therapy is of little value in the treatment of endocrinopathic amenorrhea, although in many of these it is often resorted to because of the lack of any other treatment which is any more rational or any more effective

The weight of evidence indicates that in the treatment of menopausal symptoms, proper allowance being made for difficulties in the interpretation of the therapeutic results, the estrogenic substances are of real though variable value

The treatment of gonorrheal vulvovaginitis in children by means of injections of estrogenic substance is a promising method, though much more experience with it is necessary before worth while conclusions can be drawn as to the rapidity and permanence of the bacteriologic cure, and the possible harmful by-effects of the method

At present it seems that the treatment of hemophilia with estrogenic preparations will not live up to early expectations, though here again further experience with the plan must be awaited

While estrogenic therapy is at times employed for various other indications, as enumerated in the paper, the rationale is usually poorly defined and the results are ordinarily disappointing²⁰

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M D

CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr Bernard Fontus. The views expressed by various members are incorporated in the final draft for publication. The articles will be continued from time to time in these columns. When completed, the series will be published in book form.—Ed

THERAPY OF IRITIS (IRIDOCYCLITIS) AND OF CHOROIDITIS

OUTLINE BY DR SANFORD R GIFFORD

Inflammation of the uveal tract may involve chiefly the anterior segment of the eye (iridocyclitis) or the posterior segment (choroiditis). While the search for the cause and the systemic treatment are conducted along the same principles for the two conditions, the local measures indicated in iritis are of little value in choroiditis, i e., when the anterior segment is not involved

DIAGNOSIS

Differentiation between acute iritis and acute glaucoma (q v) is of the greatest importance, as the treatment of the one is diametrically opposite to the treatment of the other, so that an error in diagnosis may produce most serious results

Characteristics of Acute Iritis and of Acute Glaucoma

	Acute Iritis	Acute Glaucoma
1 Pupil	Of affected eye smaller Reaction sluggish Posterior synechiae	Semidilated or dilated Reaction absent
2 Anterior chamber	Deep	Shallow
3 Tension	Usually decreased	Greatly increased
4 Vision	Slightly impaired	Greatly impaired
5 Pain	Referred to eye and region of ophthalmic division of fifth nerve only	Much more severe and may spread to second and third divisions of the fifth nerve

TREATMENT

1 Causal.—As delay of a few days in instituting the proper treatment may mean permanent loss of vision, a thorough search for the cause should be undertaken promptly. If at all possible, one should make, on the day the patient is first seen, a blood Wassermann test, roentgen examination of the teeth and examination of the throat and the nose, and should take a sinus roentgenogram whenever the nasal examination indicates the latter. Syphilis (q v) is the cause of from 20 to 25 per cent of cases of acute iritis. Focal infection (q v) of the tonsils in children, and of the teeth and sinuses and the prostate in adults, is next in order. In chronic iritis, tuberculosis (q v) is responsible for from 10 to 40 per cent of cases.

In cases, therefore, in which syphilis and tuberculosis can be ruled out, attention must be concentrated on the finding of the focus of infection and its prompt eradication, if at all possible. Even though this may precipitate a temporary increase in the symptoms of

iritis, it is often followed by rapid and complete relief. When, in acute cases, removal of infected teeth or tonsils does not give relief within a few days, one must search further without loss of time. Retained infected dental roots or infected areas of bone in mouths from which all teeth are said to have been removed should be searched for. The focus may be found in the genito-urinary tract in the form of gonorrheal or non-gonorrheal infection which should receive appropriate treatment. If not found elsewhere the intestinal tract and its adnexa (gallbladder or appendix) may be suspected as the source of the infection. For the therapy of these various forms of focal sepsis the sections dealing with these will have to be consulted.

Removal of the cause is of importance in the interest not only of cure but also of prevention of recurrences, which otherwise are only too common.

2 Local Measures—These are indicated in iritis, not in choroiditis.

Atropine Ointment

R Atropine sulphate	0.20 Gm
Distilled water	1.00 cc
Hydrous wool fat	2.00 Gm
White petrolatum	7.00 Gm

Mix with careful trituration and dispense in collapsible tube with eye tip.

Label: Apply to affected eye every eight hours.

(a) Mydriasis must be secured promptly in iritis and maintained until all symptoms of inflammation have disappeared, chiefly in order to prevent permanent posterior synechiae. In moderately severe cases, from 5 to 10 drops of a 1 per cent solution of Atropine Sulphate instilled every two to three hours and as soon as maximal dilatation has been secured three times daily suffice to produce this result. An ointment containing 2 per cent of the alkaloid might be preferable because of more continuous action in producing the desired effect. When the solution is used, absorption—which occurs through the cornea—is favored if the patient is recumbent and the lids are held open, so that the cornea is kept flooded. To avoid systemic poisoning, finger pressure should be maintained during this time on the lacrimal sac by the patient himself. The preliminary use of 2 per cent Cocaine Hydrochloride solution promotes the effect of the atropine as well as the patient's comfort. If this procedure does not succeed in producing mydriasis, one should not hesitate to make a single application of a small particle of the powdered alkaloid salt in the sac. If mydriasis is not secured promptly by these means, one must employ subconjunctival injection of 0.2 cc above and below the limbus of a mixture of 2 per cent Atropine Sulphate 1 part, and Solution of Epinephrine 2 parts, following the application of 2 per cent Cocaine Hydrochloride solution.

The mydriasis should be continued for at least two weeks after all symptoms have disappeared, to prevent recurrence.

Rise in intra-ocular tension and secondary glaucoma should be watched for and its presence suspected when pain sets in and failure of vision unaccounted for by opacities in the media, occurs. For its management, see Therapy of Glaucoma.

Atropine conjunctivitis may occur in susceptible individuals within a day or two. It consists of conjunctival congestion and chemosis with redness of the lid often spreading to the cheek, so as to resemble erysipelas. It calls for the discontinuance of the atropine, the use of Solution of Epinephrine diluted to one-fourth strength (1:4,000) and the application of cool compresses.

Calamine lotion may be applied to the inflamed skin. If mydriasis is still imperative, 1 per cent Scopolamine Hydrobromide solution should be employed, of which one drop at a time should be instilled with the same precautions as for atropine, as toxic symptoms occur in many persons.

(b) Heat may well be combined with the use of the mydriatic. This is perhaps best applied by pouring, by means of a spoon, a saturated solution of Boric Acid, as hot as can be tolerated, over the closed lids for fifteen minutes every three or four hours. Small heating lamps may be effectually used.

(c) Leeching is employed instead of the heat in cases in which there is much hyperemia and severe pain. Two leeches are applied near the external canthus of the eye. To make the leech bite where one desires, the animal is confined by means of a small wide mouth bottle applied with its mouth down to the area. After the leeches have dropped off, the bleeding is encouraged by means of sterile hot sponging.

3 Systemic Measures—(a) Salicylates should be employed in large doses, such as are given in the treatment of rheumatic fever (q.v.), to secure the analgesic and antiphlogistic effect of this drug. Slight nausea or tinnitus should not be considered an indication for lessening the dose nor albuminuria excepting in patients with preexisting nephritis. Hence the urine should always be examined before administration of the drug is commenced. The dose that produces the desired effect should be maintained for four or five days then cut to half and continued for several days after all symptoms of inflammation have subsided. When salicylate is not well borne, especially if it produces emesis, Neocinchophen (0.3 Gm tablets) should be given in 1 Gm doses eight to ten times a day. It is also a useful succedaneum to salicylate in long drawn out cases, provided it is not employed in cases in which liver disorder is known to be present and a careful watch for toxic symptoms is exercised.

(b) Proteotherapy should be employed in severe cases and in those resistant to salicylates which should then be stopped at least for a day or two, to permit the febrile reaction to take place unchecked, so that one can judge whether a reaction of sufficient intensity has been secured. Typhoid-paratyphoid vaccine is injected intravenously in a dose of 30 million organisms to begin with. This is increased to 50, 60 or 70 and even 100 million at subsequent injections, depending on the resulting reactions. To measure such dosage, it is necessary to employ a tuberculin syringe and to dilute the commonly used vaccine which contains 1,000 million organisms per cubic centimeter, to one tenth. This is done by drawing up 0.1 cc of the vaccine in the syringe which is then filled with physiologic solution of sodium chloride to 1 cc and the solution is mixed by means of an air bubble. A dose of 0.3 cc. of this dilution will contain 30 million organisms. The intervals between injections depend on the reaction. In critical conditions the next injection may be given when the patient has been free from fever for twenty-four hours or when the blood count has returned to normal for the same length of time. In general, the best interval between injections is two fever-free days.

Confinement in bed is, of course, necessary in all severe cases and especially during the time of salicylization or of proteotherapy.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORTS HOWARD A. CARTER, Secretary

ILLINOIS INFRA-RED LAMP ACCEPTABLE

Manufacturer Illinois Surgical Supply Company Chicago

The heating element of this lamp is a single bar type about 23½ inches long and 1½ inches in diameter and is made of ceramic material and resistance wire. Its rated capacity is about 500 watts. The burner is mounted in a 10 inch polished aluminum reflector 6 inches deep.

The upright and reflector are mounted on a flat base weighted to prevent tipping. The cross bar, supported on a hinge joint, has a freedom of motion of 7½ inches and can be rotated through an arc of almost 180 degrees. The upright may be extended to a distance of 22 inches. The maximum height is 72 inches.

One unit was tested for physical efficiency in a laboratory acceptable to the Council. When connected to a 110 volt line the current reading was 4 amperes or 448 watts. A plane in the air 70 cm in diameter 1 meter from the edge of the reflector and perpendicular to the center line through the heating element was surveyed for radiation distribution. Within a smaller area 50 cm in diameter directly in front of the heating element, the radiation distribution was relatively uniform and free from hot spots. In this 50 cm circle the radiant energy was 48 per cent more than at the remaining part of the 70 cm circle on the periphery. For such a small unit, the radiation distribution is quite satisfactory.

The unit was tried out in a clinic acceptable to the Council. From a clinical standpoint the lamp was found to be satisfactory for treatment when infra-red radiation is indicated.

The Illinois Infra-Red Lamp therefore is included in the Council's list of accepted devices.

Illinois Infra Red Lamp

VIBRATHERM NOT ACCEPTABLE

Manufacturer The Vitaphone Company Los Angeles

According to the firm this device appears to have unlimited possibilities. It is recommended for afflictions such as frequent night rising, bladder weakness, backaches and headaches, arm, leg and foot pains, sciatica, neuritis, chronic constipation, piles (hemorrhoids), lack of energy, worry and fears, sexual impotence, irritability, insomnia, decreased mental efficiency, and pelvic disorders.

The device is a vibratory massage outfit and operates only on alternating current. The unit submitted to the Council was examined along with the advertising matter. The front page of the circular 'Your Key to Health, Youth, Vitality' carries the statement 'Why You Are Old at Forty' giving one the impression that the answer is enclosed. On the same page it is stated 'Prolong Your Life—Without the Use of Drugs or the Recourse to Surgery'.

On the next page the manufacturer makes the statement that women have a pseudo prostate gland attached to the neck of the bladder and the same causes which interfere with the function of the male prostate cause similar disorders in women. Farther on on the same page it is stated that slowing up and retention of acid, caustic and poisonous material causes irritation and congestion. Then the firm writes that further neglect may compel the recourse to surgery which destroys all hope of ever again enjoying normal vigorous vitality and in bold, vigorous type it states that not one man in a hundred need face that ordeal.

On the next page, we are told "The years of research for the correct method to remove the cause of pelvic disorders, led to the invention of the VIBRATHERM."

Under the heading "Dilation" some very striking statements are set forth, and the claim is made that through their machines "a perfect therapeutic treatment is created." On pages 8 and 9 of the pamphlet under the illustration of the Vibratherm, the statement is made that "Vibratherm treatments taken in the privacy of your home will be fully as effective as those being given by physicians using our professional model."

Then there is given a great list of testimonials from men who say they have been cured by the machine as well as from physicians who have used it in their practice. As a final reminder on the back cover is given a list of the diseases for which one should use Vibratherm.

Nothing in the way of evidence has been submitted to substantiate the aforementioned doubtful statements.

In view of the unwarranted and misleading claims in the advertising matter the Council on Physical Therapy voted to omit the Vibratherm from its list of accepted devices.

ELLIOTT TREATMENT MACHINE ACCEPTABLE

Manufactured for and distributed by the Treatment Regulator Corporation Detroit and the A. S. Aloe Company St. Louis

The Elliott Treatment Machine is recommended for applying heat therapy for the treatment of inflammatory diseases of the pelvis. Treatment is accomplished by prolonged and sustained application of heat. Hot water, the temperature of which may be controlled by the physician, is circulated through anatomically shaped distensible applicators made of latex.

The machine measures approximately 17 by 11¼ inches at the bottom and 15 inches in height and weighs 25 pounds. A copper water tank holds a little over 2½ quarts of water. The top of the water tank is made of cast bronze and supports a motor, which operates on either alternating or direct current. The unit requires about 150 watts of power.

The motor propels a dual action centrifugal turbine, which is immersed in the water in the tank at all times. The centrifugal action of this pump creates a continuous pressure or outflow of the water and at the same time a continuous and steady suction for the return flow from the applicators. Each part of the pump is made of cast bronze.

The machine is an electrical device which serves two purposes: first, to heat water by electricity to a desired temperature between 100 and 130 F.

automatically maintaining such temperature as desired by thermostatic control; and, second, to pump that water through a length of hose to a rubber-bag type of applicator, withdrawing the water at the same time through another hose, thus distending that bag to fit the walls of the orifice under treatment at a constant pressure. The entire unit is quite compact, easily operated, and provided with a handle so that it may be carried without difficulty. It comes equipped with one vaginal bag and one prostatic bag.

Elliott Treatment Machine

This unit was investigated in clinics acceptable to the Council on Physical Therapy for the conditions recommended, such as inflammatory diseases of the pelvis attended by pain, backache, menstrual irregularities and chronic exhaustion. Since the evidence for the efficacy of the Elliott Machine is not complete in the treatment of sinus and eye infections, recommendation is withheld for the present. The unit was found to give good service and was superior to the hot water douche.

This machine is not accepted by the Council for the purpose of replacing those thoroughly substantiated methods used by the rank and file of the profession for the majority of mild pelvic infections, which in the past have yielded to conventional

forms of therapy. The unit's greatest value, in the opinion of the Council, will be found in the larger clinics or hospitals where the mass of material will enable a careful selection of cases requiring this form of treatment.

In view of the favorable report, the Council voted to include the Elliott Treatment Machine in its list of accepted devices for one year.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH, Secretary

THROMBOPLASTIC SUBSTANCES THROMBOPLASTIN SOLUTION-ARMOUR OMITTED FROM N N R

In view of the lack of evidence for the therapeutic value of thromboplastic substances other than those designed for external use the Council in 1930 voted to omit from New and Nonofficial Remedies preparations of thromboplastin designed for subcutaneous or hypodermic administration and revised the general article Fibrin Ferments and Thromboplastic Substances to omit any reference to such use. At present, therefore, only products intended for local use stand accepted. These are

Kephalin Armour
Fibrogen Local Merrell
Thromboplastin Solution-Armour
Thromboplastin Local Lederle
Thromboplastin Local-Squibb

During the past year there was submitted a thromboplastin for local use. In the consideration of this product a member of the Council suggested that this type of preparation might contain tetanus or Welch bacillus. In view of this, the Secretary of the Council wrote to manufacturers of various thromboplastic substances for information concerning evidence for the sterility of their products. Several of these replies were not entirely satisfactory and the Council's referee prepared a report asking the Council to authorize the Secretary to write to the manufacturers of accepted products requesting that they make satisfactory tests for the sterility of their products. Before this report could be submitted to the Council, information was received concerning an untoward incident in a large eastern hospital.

During the past four years there were observed in the institution referred to four cases of B. Welchii and three cases of B. tetani postoperative infections. It was reported to the Council that most of these occurred after prostatectomy. The occurrence caused a thorough reinvestigation of all the surgical procedures of the institution. The operating rooms were quarantined, the instruments were autoclaved in a central sterilizing room, and the efficiency of the autoclaves was controlled by temperature and pressure automatic records. Nevertheless a postoperative infection appeared from time to time. Late in 1934, according to the statement made to the Council, it seemed advisable to take a culture of Thromboplastin Armour which had been used in the prevention of postoperative bleeding. To the surprise of the investigator the Thromboplastin was found to contain B. subtilis, Staphylococcus aureus, B. proteus, enterococcus and B. Welchii. This information was communicated to the Council.

As a result of this incident, a bacteriologic examination of samples of commercial thromboplastic preparations was made for the Council. The work was carried on under the supervision of one of the members of the Council, who himself made cultures from six of the samples. The following is a report summarizing the procedure and results of the examination.

Report on Bacteriologic Examination of Thromboplastic Preparations

All of the specimens except one were in unopened containers purchased on the open market by the Secretary or his agents in Chicago and other cities. Four bottles of Armour's Throm-

boplastin Solution and two bottles of Squibb's Thromboplastin were received through the Secretary from Dr. Gregory Schwartzman of New York.

The containers were opened with sterile precautions and material was withdrawn for stains and cultures. Cultures were made on blood agar plates, dextrose infusion broth and cooked meat medium. These were incubated aerobically and anaerobically at 34 or 37.5 C. The amounts of each preparation used for the inoculation of tubes containing about 10 cc. of liquid mediums were 0.01, 0.1 and 1 cc. Loopsful were streaked on plates. Animals were inoculated with a few of the cultures. No attempt was made to identify all the bacteria in all the cultures.

I. Thromboplastic preparations of Armour & Co., Chicago. Thromboplastin Solution-Armour. Listed in New and Nonofficial Remedies, 1934 p. 209. Six 25 cc. bottles examined. Each bottle had a cellophane cover over a bakelite screw cap.

- (1) Thromboplastin Solution Armour 25 cc. bottle Lot No. 101119. Expiration date Nov. 10 1935. Numerous bacteria, about 1000 colonies per cubic centimeter as determined from plates. Various types of spore bearing bacilli. No gas formers. No cocci found.
(13) Thromboplastin Solution Armour 25 cc. bottle Lot No. 101175. Expiration date Dec. 19 1935. Numerous bacteria, gram negative and gram positive spore bearing bacilli possibly eleven different varieties. No cocci found. B. Welchii (or a closely related organism) isolated from anaerobic culture. This organism was pathogenic for a guinea pig.

The following specimens in unopened bottles were received from Dr. Schwartzman:

- (C) Thromboplastin Solution Armour Lot No. 101176 25 cc. bottle. Expiration date Oct. 11 1935. Numerous varieties of aerobic and anaerobic bacteria chiefly spore bearing bacilli. A gas forming organism resembling B. Welchii found in anaerobic cultures.

- (D) Thromboplastin Solution Armour Lot No. 101176. Expiration date Oct. 11 1935. Many varieties of aerobic and anaerobic spore-forming bacilli. Streptococcus viridans? Diphtheroids. Anaerobic bacillus resembling B. Welchii present.

- (E) Thromboplastin Solution Armour, Lot No. 101173. Expiration date June 6 1935. 25 cc. bottle. Several varieties of aerobic and anaerobic spore-forming bacilli. Gas forming anaerobic bacillus resembling B. Welchii.

- (F) Thromboplastin Solution Armour Lot No. 101176. Expiration date Oct. 11 1935. 25 cc. bottle. Several varieties of gram negative and gram positive spore bearing bacilli in aerobic and anaerobic cultures. Colonies of gram positive cocci. Gas forming organism resembling B. Welchii in anaerobic cultures.

Cultures of the Armour preparations had a putrid cheesy odor. There were terminal spore-bearing bacilli in the anaerobic cultures. Mice were inoculated with material from five of these cultures. None developed tetanus.

II. Thromboplastic preparations of Ciba Company Inc., New York. None listed in New and Nonofficial Remedies.

- (7) Coagulen Ciba (Sterilized). Carton of five 5 cc. ampules. Control No. 41863. No expiration date. One ampule examined. Sterile.

- (8) Coagulen Ciba (Sterilized). Carton containing one 20 cc. ampule. Control No. 43163. No expiration date. Sterile.

- (12) Coagulen Ciba (Sterilized). Control No. 39443. No expiration date. One ampule examined from carton of five. Sterile.

- (17) Coagulen Ciba (Sterilized). Carton with one 20 cc. ampule. No expiration date. Control No. 28253. Sterile.

III. Thromboplastic preparations of Lederle Laboratories, Inc., Pearl River, New York.

- (4) Thromboplastin Local Lederle. Listed in New and Nonofficial Remedies 1934 p. 210. 20 cc. vial. Lot No. 118 H 1585 A. Expiration date 5/1/36. Sterile.

- (16) Thromboplastin Local Lederle. Lot No. 118 H 1619 A. Expiration date 6/3/36. 20 cc. vial. Sterile.

IV. Thromboplastic preparations of William S. Merrell Co., Cincinnati.

- (5) Fibrogen Local Merrell No. 92. Listed in New and Nonofficial Remedies 1934 p. 208. 7 cc. bottle. Expiration date Nov. 1934. Sterile.

- (6) Fibrogen Oral Merrell No. 89. Not listed in New and Nonofficial Remedies. Lot No. 4 K 8022. Expiration date March 1936. Cartons of 3 cc. vials. Sterile.

- (10) Fibrogen Local Merrell No. 92. Lot No. 4 F 5939. Expiration date December 1935. 7 cc. bottle. Sterile.

- (15) Fibrogen Oral Merrell No. 89. Lot No. 4 B 1624. Carton of 3 cc. vials. Expiration date April 1935. Sterile.

V. Thromboplastic preparations of Parke, Davis & Co., Detroit.

- (11) Hemostatic Serum (Lapenta) Bio 72. Parke Davis & Co. Lot No. 022094A. Expiration date 9/15/37. 5 cc. vial. Sterile.

VI Thromboplastic preparations of E R Squibb & Sons, New York

- (2) Thromboplastin Local Squibb Listed in New and Nonofficial Remedies, 1934 p 210 Lot No 53088 20 cc vial Expiration date 7 23 36 Sterile
- (3) Thromboplastin Local Squibb Lot No 52315 20 cc vial Expiration date 3 1 36 Sterile
- (9) Thromboplastin Local Squibb Lot No 53338 20 cc vial Expiration date 10 15 36 Sterile
- (14) Thromboplastin Local Squibb Lot No 51429, 20 cc vial Expiration date 11 27 35 Sterile
- (A) Thromboplastin Local Squibb 20 cc vial received unopened from a correspondent Lot No 53345 Expiration date Nov 23 1936 Sterile
- (B) Thromboplastin Hypodermic Squibb Not listed in New and Nonofficial Remedies Unopened 20 cc vial received from a correspondent Lot No 53611 Expiration date Nov 13 1936 Sterile

VII Thromboplastic preparations of U S Standard Products Co., Woodworth, Wis Not listed in New and Nonofficial Remedies

- (18) Thromboplastin Local U S Standard Products Co., 20 cc vial Marked in pencil 447 Serial No 7 A1 Expiration date Nov 7 1934 The carton had been opened before it was received by the examiner Cultures spore forming aerobic bacilli No gas formers

Summary

PREPARATION EXAMINED	RESULTS
I Thromboplastin Solution-Armour Six 25 cc. bottles	All specimens contained numerous bacteria, chiefly spore-bearing aerobes and anaerobes Streptococci and diphtheroids in some. Organism closely resembling B Welchii found in five of the six samples
II Coagulen Ciba* Four ampules	Sterile
III Thromboplastin Local, Lederle Two 20 cc. vials	Sterile
VI Fibrinogen, Local and Oral, Merrell Four vials	Sterile
V Hemostatic Serum (Lapenta), Parke, Davis & Co One vial	Sterile
VI Thromboplastin, Local and Hypodermic, Squibb Six vials	Sterile
VII Thromboplastin Local—U S Standard Products Co One vial	Package previously opened. Spore-bearing bacilli, aerobic

No tetanus bacilli were found in any specimen

* Coagulen Ciba was omitted from N N R in 1920 See Reports of the Council on Pharmacy and Chemistry 1920 p 53

The Council considered the foregoing report and as a result voted to omit Thromboplastin-Armour from New and Nonofficial Remedies until satisfactory assurance is given that its manufacture is conducted under such conditions as to preclude the danger of contamination, and until such time as a number of specimens found on the market shall have been found to be sterile. The Council voted further that all manufacturers of accepted thromboplastic substances be requested to submit evidence of the sterility of their respective products and that no thromboplastic substance be accepted for New and Nonofficial Remedies until satisfactory evidence is given that the preparation is sterile.

When the foregoing report was sent to Armour & Co the firm promptly replied stating that it had confirmed the findings of the Council. It immediately withdrew Thromboplastin Solution-Armour from the market and has stated that it will not promote the product in the future. Concerning the difficulty of sterility the firm stated

We confirm the Council's findings as far as nonsterility of our Thromboplastin Solution is concerned. We should however like to make the following comments on the referee's report. To any one not intimately acquainted with bacteriology its nomenclature and group classification the referee's report may readily convey the idea that our Thromboplastin Solution was grossly contaminated with the most virulent pathogenic organisms. The use of a loose term like Welchii like organism might readily include nonpathogenic organisms.

We have manufactured Thromboplastin Solution according to the method of Hess since 1917 without a single complaint until the present difficulty arose. As soon as the matter was called to our attention the product was withdrawn from the market as we do not want any of our preparations subjected to criticism. The distribution of Thromboplastin

Solution has been limited and confined to a few of the larger cities in this country. Our yearly sales amounted to only a few hundred bottles. For these reasons we feel confident that the withdrawal has been efficient.

It has always been our rule to retain reserve samples from each batch of products made and offered for sale by us. As a consequence we have reserve samples representing the various lots of Thromboplastin Solution examined by the referee. We have made a very careful study of the bacterial flora of these reserve samples. In no instance have we been able to identify or isolate gas gangrene (Cl Welchii) or tetanus (Cl tetani) organisms. Intraperitoneal injections of actively growing anaerobic cultures from the various lots of Thromboplastin Solution into a number of guinea pigs with absolute negative results further show the absence of specific pathogens including Cl Welchii and Cl tetani. Intimate application of Thromboplastin Solution and cultures recovered from Thromboplastin Solution to freshly lacerated surfaces of a number of laboratory animals failed to produce local or systemic infections all wounds healing spontaneously.

We therefore maintain that while our Thromboplastin Solution was not sterile it did not contain pathogenic organisms.

Since receiving your first letter in regard to the sterility of Thromboplastin Solution we have made a very careful investigation of the whole situation. We have found it a difficult matter to produce absolute sterility in Thromboplastin Solution without a material decrease in blood clotting properties. Filtration through Berkefeld filters of a suspension of brain tissue particles such as Thromboplastin Solution is of course out of the question. The product has been dispensed in stoppered or capped bottles but since cresol which is specified as a preservative for Thromboplastin Solution in N N R is not a perfect germicide the product cannot be considered sterile after the stopper has once been opened. For these reasons we have definitely decided to discontinue the production of Thromboplastin Solution until such time when satisfactory methods of sterilization and proper and safe means of dispensing the product have been worked out.

The Council commends Armour & Co for the prompt action it has taken. The Council feels however, that it owes a duty to the profession to keep it informed so that the future may profit by experience of the past; therefore, it deemed it necessary to authorize publication of this report even though the firm has withdrawn the product from the market. The Council points out that the presence of the B Welchii type of organisms was detected in the examination conducted under the auspices of the Council and also that the presence of B Welchii was reported by the investigator in the hospital who first discovered the contamination.

PRELIMINARY REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
PRELIMINARY REPORT PAUL NICHOLAS LEECH Secretary

GONOCOCCUS BOUILLON FILTRATE
(GONOCOCCUS TOXIN) II

A preliminary report on this preparation, marketed by Parke, Davis & Co under the name 'Gonococcus Filtrate (Corbus-Ferry),' was issued by the Council in 1932 (THE JOURNAL, Feb 13 1932, p 554). At that time the Council postponed consideration of this product to await the development of confirmatory evidence of its clinical value.

In 1934 Parke Davis & Co renewed its request for Council consideration submitting the manuscript of a report by Cumming and Burhans, which had already been proposed for publication in THE JOURNAL. The paper by Cumming and Burhans reports favorable results in the treatment of all stages of gonorrhea with gonococcus filtrate (Corbus-Ferry) and compares the results favorably with those obtained by local and foreign protein methods. It is definitely shown that intradermal administration provokes a prompt, transient exacerbation of symptoms and increases discharge, followed by recession. The authors fail to compare the necessary durations of treatment by gonococcus filtrate with those in other methods of treatment and fail to state the comparative incidence of complications or recurrences, or the number of cases treated by other methods.

Undoubtedly the paper presents suggestive, but not conclusive evidence that more prompt recession of symptoms and discharge occur with this treatment, but no direct comparison of control methods is made.

While the evidence submitted since publication of the first preliminary report of the Council is favorable to the use of the product the Council feels that because of its inconclusive nature it is not sufficient to warrant the acceptance of the product at this time. The Council has therefore reaffirmed its previous decision, postponing consideration of Gonococcus Filtrate (Corbus-Ferry) to await the development of confirmatory evidence of its clinical value.

EFFICACY OF TYPHOID VACCINATION

Although morbidity and mortality rates from typhoid in the United States continue to be low, the efficacy of protective typhoid vaccination continues to be a matter of more than academic importance. The most extensive information on this question is available in the results obtained by the United States Army and Navy.

Cook¹ has recently discussed typhoid prophylaxis in the United States Navy. Compulsory vaccination was ordered in 1911 and by the end of 1912 almost every person in the navy had received three injections of typhoid vaccine. Two periods are thus available for study: twenty-two years before compulsory typhoid inoculation and twenty-two years after. The improvement in sanitary conditions since 1890 and the subsequent reduction in typhoid in the general population, however, necessitate closer scrutiny than the mere record of lowered morbidity and mortality since that time. A comparison between the annual deaths in the navy and in the registration area of the United States gives better evidence of the value of inoculation, since improvements resulting from sanitation may be assumed to be roughly similar. From 1900 to 1905 the death rates were considerably higher in the navy than in the registration area, from 1905 to 1911 they were roughly parallel, but after 1912 there was a sharp drop in the navy as contrasted with a gradual decline in the registration area. While not perhaps, conclusive, this fact is at least highly suggestive.

Similar lowering of the case and fatality rates from typhoid have been manifest in the United States Army.² Patterson, however, presents his material in a somewhat less convincing manner than that for the navy. The fact that there were only 1,529 admissions to sick report from typhoid from more than four million mobilized during the World War is a matter of pride, but sanitary knowledge was so much improved that it is not justifiable to assign this low typhoid rate even

largely to vaccination. That vaccination was one of the important factors is probable but is not proved by Patterson's report.

The other major question with respect to typhoid inoculation is the selection of the strain to be used. This question was carefully studied in 1908, at which time the "Rawlins" strain was chosen. It has been in use since that time. The adequacy of this choice has been periodically reviewed and the present status of opinion has been outlined by Hawley and Simmons.³ They concluded that "the Rawlins strain may not be the best typhoid vaccine strain, but it is our belief that the Army Medical School substrain is no worse today than it ever was." They felt that the vaccine could be improved by increasing its bacterial content within the limits of safety. Further careful investigations are being conducted concerning the efficiency of this strain with a view to ascertaining whether the same strain should be continued or a new one developed. Meanwhile it can be safely reiterated that prophylactic typhoid vaccination is a safe and reasonably trustworthy procedure.

RETARDED GROWTH AND LONGEVITY

In the past studies in nutrition have been concerned chiefly with maintenance of normal health and production of a rapid rate of growth. The latter, in view of the ease with which it may be measured, has served as an indicator for a great many investigations on diet. Foods or food factors that promoted the most rapid rate of gain were generally considered the most advantageous, the idea has gained currency that the promotion of rapid growth is somehow associated with an enhanced state of health. As McCay and Crowell⁴ of Cornell University have stated: "The philosophy which dominates the field of nutrition assumes that a young animal which grows rapidly is the ideal for maximum health both during the growing period and during adult life." These authors have pointed out several of the factors that have served to promote this point of view. Among these are the widespread employment for dietary studies of the white rat, which grows to maturity in the short period of about three months, the direct application of studies in growth to stock raising, in which rapid gain is economically profitable and the widespread interest in infant and child nutrition, in which the rate of growth is used as a measure of dietary adequacy. But in most of the studies that have been made, the effects of the rate of growth in early years on the subsequent health, susceptibility to disease and life span of the adult have received little attention. This is the more surprising as a negative correlation between rate of growth and longevity has

⁴ McCay C. M. and Crowell Mary F. Prolonging the Life Span. *Scientific Monthly* 30: 405 (Nov.) 1934.

long been suspected. Thus the Cornell investigators quote, among others, Lord Francis Bacon (1561-1626)

It seems to be approved by experience that a spare and almost Pythagorean diet, such as is prescribed by the stricter orders of monastic life or the institutions of hermits, which regarded want and penury as their rule, produces longevity.

Animals which come later to perfection are longer lived.

To grow long and slowly is a sign of longevity and the taller the stature the better the sign. But on the other hand, rapid growth to a great stature is a bad sign but to a shorter stature less bad.

I would have men duly to observe and distinguish that the same things which conduce to health do not always conduce to longevity.

Again there are other things very beneficial in prolonging life yet that are not without danger to the health unless guarded against by proper means.

Until relatively recently, little reliable data were available to substantiate such theses, but increasing information more and more confirms the observations of Francis Bacon and of others who wrote to the same effect before him and since. McCay² has summarized the results obtained in several different species. Prolongation of life associated with a retarded rate of growth has been noted in such divergent forms as rats,³ insects,⁴ brook trout⁵ and even cantaloup seedlings⁶. For instance, brook trout in which growth was retarded lived about twice as long as those that grew more rapidly. McCay and Crowell have proposed the hypothesis that something is consumed in growth that is essential for the maintenance of life. This concept as will be noted later, has received independent support in the mathematical studies of Wetzel.⁷

McCay and Crowell recently reported the results of a long series of observations on rats maintained on diets adequate in vitamins, proteins, inorganic salts and fats but deficient in total calories. At the time of weaning, 106 rats were divided into three groups, one of thirty-four animals and the other two of thirty-six each. The members of one group were allowed to grow normally, those of the second were forced to grow very slowly by limiting food intake, and those of the third group were allowed to grow normally for two weeks and were then restricted in food allowance. The animals in which growth was retarded were kept at a stationary weight for from one to four months, at this time a weight increase of about 10 Gm was permitted. Not until after more than twenty-eight months were these rats permitted to eat freely.

The animals that were kept on a restricted food intake for long periods outlived by a wide margin those that were allowed to eat their full from the time of weaning.

Thus the average life span of those that grew rapidly was 509 days for the males and 801 days for the females. Of the two groups the growth of which was retarded, thirteen animals (five males and eight females) were still alive at the end of 1,200 days, not one of the other animals lived that long. Of the rats in the two retarded groups that died, the mean life span was 792 and 883 days respectively for the males and 755 and 824 days respectively for the females. It has been estimated that ten days in the life of a rat is roughly equivalent to one year in the life of a man, on this basis the thirteen surviving slow-growing rats lived for a period exceeding the human equivalent of 120 years. The hair of the retarded animals remained fine and silky long after that of the fast-growing rats had become coarse and unkempt. However, most of the former had become partly or entirely blind.

The inverse relationship of rate of growth and time of onset of senility is also apparent from other investigations. Evans⁸ has pointed out that animals injected chronically with preparations containing the growth hormone of the hypophysis show evidence of premature senility. This occurs despite the fact that, as Lee and Schaffer have shown, administration of the pituitary growth hormone results in retention of juvenile chemical characteristics by the tissues. It is not known, however, how long these properties, which normally are found only in young animals, may be retained under prolonged administration of this growth-promoting principle, studies covering an adequately long period have not yet been reported. Other implements for the study of these extremely interesting problems are available, such as thymus extracts, which greatly increase the rates of growth and maturity,⁹ and Hanson's pineal extract, which has been found to retard growth.¹⁰ But as yet no information directly bearing on longevity has been reported by the experimenters who have been using these preparations.

Evidence is also available from studies made directly on man that an excessive rate of growth is harmful. Wetzel,⁷ in his brilliant mathematical work on the 'motion of growth,' has demonstrated conclusively that excessive rate of gain during infancy and childhood is associated with an even greater rate of wasteful heat production and that this may have grave consequences. It is apparent that some of the current tenets in the field of nutrition require reconsideration in an effort to determine the optimal rate of growth for each period in life. The relationship which Wetzel has established mathematically between heat production and growth provides an admirable basis for this reconsideration.

CULLEN'S SIGN IN RUPTURED ECTOPIC PREGNANCY

In 1919 Dr Thomas S Cullen¹ of Baltimore reported a case in which a woman, aged 38, for three weeks had had pain in the right lower quadrant of the abdomen with intermittent attacks of abdominal distention. One week after the onset the umbilical region suddenly became bluish black, although there had been no injury in this region. Prior to opening the abdomen of this woman, Dr Cullen dictated the following: "The bluish black appearance of the navel unassociated with any history of injury, together with the mass to the right of the uterus, makes the diagnosis of extra-uterine pregnancy relatively certain, although the patient has not missed any period and although there has been no uterine bleeding." At operation the abdomen was found filled with dark blood and attached to the fimbriated end of the right tube was an extra-uterine pregnancy. Since this report was published, bluish discoloration of the umbilicus in ruptured ectopic gestation has been observed and reported by numerous writers in this country and abroad. In *THE JOURNAL*, March 4, 1922, Cullen's original colored picture of this condition was reproduced in Novak's article. Recently Smith and Wright² reported two cases in the *Lancet*. In one of their cases the bluish discoloration appeared in the lower third of an old appendectomy scar, which had been the site of a drainage tube. In their second case the discoloration closely resembled Cullen's original colored illustration. Many other cases have no doubt been observed but not reported.

The discoloration accompanying Cullen's sign is not always blue, the color depends on the degree of oxidation of the deposited blood pigments and may be any of the various hues that are known to follow an ordinary bruise. As Novak said, a dark bluish discoloration about the umbilicus probably would indicate a recent hemorrhage, and a greenish yellow or orange color would suggest that the intra-abdominal blood had been present some time. No discoloration at all can be expected when the hemorrhage is so rapid that the patient comes under observation soon after it occurs. Likewise, in cases of ruptured ectopic pregnancy that are not associated with intraperitoneal hemorrhage of considerable degree, Cullen's sign probably would not be present. Bluish discoloration around the umbilicus is not a pathognomonic sign of ruptured ectopic pregnancy, for it has been found in other abdominal conditions. Zum Busch reported an example caused by hemorrhage into an adherent ovarian cyst. Schumann records a case which he diagnosed ruptured ectopic pregnancy largely on the basis of Cullen's sign, and

laparotomy showed a two months intra-uterine pregnancy associated with purulent bilateral salpingitis, but no free blood in the peritoneal cavity. Sternberg described a case in which bluish discoloration of the umbilicus was associated with hemorrhagic ascites due to adenocarcinoma of the liver. Stutzer observed a brownish blue discoloration of the abdominal wall about the umbilicus in a case without hemorrhagic pancreatitis. After reviewing the literature, Smith and Wright conclude that bluish discoloration about the umbilicus is a rare indication of intraperitoneal hemorrhage. For example, Stein in 106 cases and Jones in ninety cases did not observe Cullen's sign. In a clinical analysis of 410 cases of ectopic pregnancy at Bellevue Hospital, Lavell found that Cullen's sign was rarely seen, but it was observed twice in the same patient. In a study of 167 consecutive cases at the University of Pennsylvania, Behney found that Cullen's sign was noted once. Novak believes however that, to all intents and purposes, Cullen's sign may be considered especially applicable to the diagnosis of ruptured extra uterine gestation.

Several theories have been proposed to explain this phenomenon. The most plausible explanation seems to be found in the lymphatics of the umbilical region. The changing shades of colors may be explained as due to the oxidation of absorbed blood pigments traveling in lymphatics connecting the umbilicus with the peritoneal cavity.

Current Comment

A BLOOD TRANSFUSION CONFERENCE

It is doubtful whether the practice of blood transfusion has been more extensively studied anywhere in recent years than in Soviet Russia. Word has just been received of a blood transfusion conference that took place in Moscow in February and was attended by representatives of many branches of the Hematology and Blood Transfusion Institute from different sections of the Soviet Union. The director of this institute, Dr Bradasaroff, pointed out that at present blood is being saved for periods of from fourteen to twenty-two days for purposes of blood transfusion, and a few cases are reported in which blood preserved up to thirty-four days has been used. In the preservation of blood, from 5 to 6 per cent citrate solution is used as well as dextrose-citrate and a special formula developed by that institute and apparently of secret composition. Blood transfusions have been made in approximately 1,000 cases with blood obtained from dead bodies within six hours after death. It would seem that such blood possesses the property of remaining liquid because of fibrinolysis and thus may be preserved without added citrate. The theory was advanced by S. S. Bruchanenko that the blood of the corpse remains liquid because of the presence of a large amount of antithrombin, which in the case of sudden death enters into the blood from the lungs. Extensive reports were

¹ Cullen, T. S. Bluish Discoloration of the Umbilicus as a Diagnostic Sign Where Ruptured Extra Uterine Pregnancy Exists from Contributions to Medical and Biological Research dedicated to Sir William Osler in Honor of His Seventieth Birthday July 12 1919 by His Pupils and Co Workers.

² Smith, Irwin and Wright, F. J. Cullen's Sign in Ruptured Ectopic Gestation with a Report of Two Cases. *Lancet* 1: 930 (April 20) 1935.

read in this conference on the selection of a donor, the complications of blood transfusion and the practical application of methods of combining blood transfusion with the administration of iron and other therapy. Some interesting reports were also presented on the possibility of transfusion of small doses of incompatible blood as well as of animal blood in order to produce a stimulating reaction in the treatment of severe infections. Among the disease conditions in which blood transfusion had been extensively used were scurvy, pellagra, malaria and gynecologic conditions.

June 4 The Crippled Child W. W. Bauer, M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Personal—Dr. William D. Gaines, Lafayette, has been appointed physician to the state prison at Atmore.—Dr. Cornelius S. Hagerty, resident pathologist at Presbyterian Hospital, Chicago, has received an appointment as assistant professor of bacteriology and pathology at the University of Alabama School of Medicine.

Bill Introduced—H. 300 proposes to prohibit the sale or distribution of barbitol, sulphonethylmethane (trional), sulphonmethane (sulphonol), diethylsulphon diethylmethane (tetronal), paraldehyde and chloral or chloral hydrate and any derivatives, compounds or mixtures of any of the foregoing drugs possessing hypnotic properties or effects, except on the written prescription of a licensed physician.

Society News—Dr. James S. McLester, Birmingham, President-Elect of the American Medical Association, among others addressed the Tuscaloosa County Medical Society recently on "Present Status of Kidney Function Tests."—Speakers before the Northeastern Division of the Medical Association of Alabama in Talladega recently, in joint session with the Talladega County Medical Society, were Drs. John A. Martin, Montgomery, on medical legislation, Clarence K. Weil, Montgomery, on fever, and Felix M. T. Tankersley, Montgomery, on conservative treatment of sinus infections.—Dr. Roy R. Kracke, Emory University, addressed the Jefferson County Medical Society, Birmingham, April 15, on "Relation of Drug Therapy to Agranulocytosis."

DELAWARE

Society News—Dr. Richard A. Kern, Philadelphia, addressed the New Castle County Medical Society in Wilmington, March 15, his subject was "Clinical Allergy." Dr. Louis H. Clerf, Philadelphia, discussed "Cancer of the Lower Air Passages," April 16.

Quarantine Station Reopened—The U. S. Quarantine Station at Reedy Island was reopened, April 1, for inspection of vessels, after having been closed for several years. Dr. Barton Brown, acting assistant surgeon who has been at the immigration station at Gloucester, N. J., is in charge under the direction of Dr. Charles W. Vogel, medical director and officer in charge of the Marcus Hook, Pa., quarantine station.

FLORIDA

Bill Passed—H. 29 has passed the house and the senate, proposing to provide for a system of compensating workmen for injuries arising out of and in the course of their employments and for such diseases or infections as naturally or unavoidably result from such industrial injuries. The employer is to furnish medical, surgical and other remedial treatment, nursing and hospital service, medicines, crutches and apparatus for such period as the nature of the injury or the process of recovery may require. Only in the event that the employer fails to furnish the services after request by the workman, is the workman to be allowed the privilege of selecting his own physician at the employer's expense.

Bills Introduced—H. 831 proposes to repeal the existing naturopathic practice act and to enact a new law creating a board of naturopathic examiners and regulating the practice of naturopathy. The bill proposes to define naturopathy as "the use of and practice of physiological, mechanical and material health sciences to aid in purifying, cleansing and normalizing human tissue for the preservation or restoration of health according to the fundamental principles of anatomy, physiology, and applied psychology as may be required." Naturopathic practice employs, among other agencies, phytotherapy, dietetics, psychotherapy, suggesto-therapy, hydro-therapy, zone-therapy, biochemistry, external applications, electro-therapy, mechanotherapy, helio-therapy, mechanical and electrical appliances, hygiene, first-aid, and sanitation." H. 854 proposes to authorize the state tuberculosis board to divide the state into not more than five districts and to establish and operate in each district a sanitarium for the treatment of persons suffering from tuberculosis. The board is to be authorized to obtain loans from the federal government for the erection of such sanitariums.

GEORGIA

Commemoration of Crawford Long—The annual observance of Crawford W. Long Day was held throughout the state March 30, according to the *Bulletin* of the Fulton County Medical Society. The celebration marks the discovery of ether anesthesia by Dr. Long in 1849. The program this year centered around the University of Georgia, Athens, where Long graduated with the degree of master of arts in 1835. The orator was Dr. Max Cutler, Chicago. At Jefferson a plaster bust of Long made by Dr. George H. Noble, Jr., Atlanta, was unveiled. A portrait representing Dr. Long in his later years was given to the Crawford W. Long Memorial Hospital, Atlanta, by the Children of the Confederacy, March 31. On this occasion Mrs. Eugenia Harper, a daughter of Dr. Long, presented to Dr. Cutler a paper knife made of wood from the mantel that formerly stood in her father's office.

ILLINOIS

Industrial Meeting—The Central States Society of Industrial Medicine and Surgery will meet in Rockford, May 21. Included on the program will be a symposium on fractures by Drs. Ralph M. Carter, Green Bay, Wis., William R. Cubbins, James J. Callahan, Carlo S. Scuderi and George L. Apfelbach, Chicago, addresses by Drs. Adrien H. P. E. Verbruggen, Chicago, on "Injuries of the Brain and Spinal Cord", Clarence O. Sappington, Chicago, "Occupational Disease Hazards" and Frederick W. Slobo, Chicago, "Injection Treatment of Herma."

State Medical Meeting at Rockford—The eighty-fifth annual meeting of the Illinois State Medical Society will be held at Rockford at the Faust Hotel, May 21-23, under the presidency of Dr. Charles S. Skaggs, East St. Louis. The Winnebago County Medical Society will be host. Dr. James S. McLester, Birmingham, Ala., President-Elect, American Medical Association, will deliver the oration in medicine. Dr. Martin Nordland, Minneapolis, will give the oration in surgery, on "The Role of Surgery in the Disturbances of the Thyroid."

Gland" According to the tentative program there will be symposiums on cataract and obscure fevers. In addition, papers will be presented by the following physicians, among others:

- Dr. Clarence A. Earle, Des Plaines: Importance of Intradermic Reactions as an Aid to Diagnosis and Degree of Susceptibility to Asthma.
 Dr. Michael Zeller, Chicago: Leukopenic Index in Intractable Asthma.
 Dr. Maximilian J. Hulieny, Chicago: Roentgenology of the Alimentary Tract.
 Dr. Dallas B. Phemister, Chicago: The Surgery of Bone Tumors.
 Dr. James C. Thomas, Rogers, Urbana: Viscerospasms—Glénard's Disease.
 Dr. Joseph Greengard, Chicago: Passive Immunity in Infants and Their Response to Diphtheria Toxoid.
 Clarence W. Muchlberger, Ph.D., Chicago: Blood Grouping Tests in the Medicolegal Determination of Nonpaternity.
 Dr. Perry B. Goodwin, Peoria: Roentgen Study of Lesions of the Urinary Bladder.
 Dr. Robert A. Arens, Chicago: Differentiation of Radiopaque Shadows in the Right Upper Quadrant.

The secretaries conference will be held Tuesday morning and among other speakers will be addressed by Dr. Olm West, Secretary and General Manager American Medical Association on 'Medical Economic Problems of Today and the Future.' A special pediatric program will also be held Tuesday morning. The veterans' service committee will hold its annual dinner Tuesday evening.

Chicago

Dr. Leary Gives Hektoen Lecture—Dr. Timothy Leary, professor of pathology, bacteriology and medical jurisprudence, emeritus, Tufts College Medical School, Boston, will deliver the eleventh Ludwig Hektoen Lecture of the Frank Billings Foundation at Thorne Hall, Northwestern University, May 24. His subject will be "Atherosclerosis, the Important Form of Arteriosclerosis, a Metabolic Disease."

Dr. Wilder Awarded the Dana Medal—The Leslie Dana Gold Medal of the National Society for the Prevention of Blindness will be awarded to Dr. William H. Wilder, emeritus professor of ophthalmology, Rush Medical College, Chicago, at ceremonies in St. Louis today, May 18. Dr. Wilder was selected for the award, given in recognition of his work in the conservation of vision, by the national society in cooperation with the St. Louis Society for the Blind, one of whose directors is the donor of the medal. Dr. Wilder, a graduate of the Medical College of Ohio in 1884, served as professor of ophthalmology at Rush from 1907 to 1926. In 1907-1908 he was chairman of the Section on Ophthalmology of the American Medical Association, in 1918 president of the American Ophthalmological Society and in 1931 president of the American Academy of Ophthalmology and Otolaryngology. At present he is secretary of the American Board of Ophthalmology and vice president of the Illinois Society for the Prevention of Blindness. He has written many articles on ophthalmic surgery and has collaborated in several books dealing with his specialty.

Society News—Speakers at the meeting of the Chicago Gynecological Society, May 17, were Drs. George de Tarnowsky, on tubal reimplantation, Henry Buxbaum, outpatient obstetrics, William A. Thomas, Edward D. Allen and Carl Philip Bauer, toxemia of pregnancy. The operative clinical meeting was held in the morning of the same day at St. Luke's Hospital.—Drs. Willis C. Campbell, Memphis, Tenn., and John D. Claridge addressed a joint meeting of the Chicago Orthopedic Society and the Institute of Traumatic Surgery, May 10, on "Operative Procedures for Rupture of the Crucial and Lateral Ligaments of the Knee" and "Bilateral Traumatic Dislocation of the Hips," respectively.—Drs. Ruth Tunnicliff and George Milles, among others, addressed the Chicago Pathological Society, May 13, on "Effect of Dissociation of Streptococci on Their Fibrinolytic and Antifibrinogenic Activity," respectively.—The Chicago Tuberculosis Institute held its annual meeting, May 10, with a program, including, among others, Drs. Midian O. Bousfield, speaking on "Tuberculosis and the Negro" and Max Biesenthal, "Thirty Years of Work in Tuberculosis."

INDIANA

Specialty Society Meeting—Dr. Joseph R. Dillinger, French Lick, was elected president of the Indiana Academy of Ophthalmology and Otolaryngology at its annual meeting in Indianapolis, April 10. Drs. George E. Shambaugh, Jr. and Thomas D. Allen, Chicago, were guest speakers, on "Significance of Diaplacusis in Ménière's Syndrome" and "Standards in Ophthalmologic Practice," respectively. Next year's meeting will be held in Martinsville.

Annual Graduate Course—Indiana University School of Medicine will conduct its annual graduate course in general medicine and surgery and the specialties May 20-June 1. The mornings will be given over to clinics and the afternoons to

discussions. Out of state speakers at the evening sessions will include Drs. Walter L. Bierring, Des Moines; Thomas G. Orr, Kansas City; Arlie R. Barnes, Rochester; Munn and Preston Kyes, Chicago. No registration fee will be charged to Indiana physicians. Out of state physicians, however, will be charged \$10. Further information may be had from the registrar of Indiana University School of Medicine, Indianapolis.

IOWA

Personal—Dr. Frank W. Dean, Council Bluffs, has been made a life member of the Iowa State Medical Society.

Annual Renewal Fees Due Before June 1—All licenses to practice medicine and surgery in Iowa expire annually on June 30. To renew such a license a licensee must make a written application to the state department of health before June 1, enclosing the renewal fee of \$1. If a license expires by reason of the licensee's failure to renew it, it can be reinstated without reexamination only on the recommendation of the board of health and the payment of the overdue fees.

Society News—Dr. Charles H. Arnold, Lincoln, Neb., addressed the Black Hawk County Medical Society, Waterloo, April 16, on "Choice of Anesthesia." At the February meeting the society adopted a resolution endorsing the stand of the House of Delegates of the American Medical Association at the special meeting in Chicago, February 15-16, against socialized medicine. Copies were sent to senators and congressmen.—A special meeting of the Des Moines Academy of Medicine and the Polk County Medical Society will be addressed, May 20, by Dr. Richard H. Jaffe, Chicago, on "Tumors of the Ovaries with Special Reference to Their Hormone Action." A symposium on cardiovascular renal disease was presented before the meeting, April 30, by Drs. Charles C. Walker, Orono, W. King, Wilbert W. Bond and Daniel J. Glomset.

KENTUCKY

Memorial to Jane Todd Crawford—The Kentucky State Medical Association is to unveil a monument, May 30, in McDowell Park, Danville, to Jane Todd Crawford, the woman on whom Ephraim McDowell performed the first ovariectomy, in 1809. Dr. Stewart R. Roberts, Atlanta, will deliver the memorial address and brief addresses will be made by Dr. Morris Fishbein, Chicago, editor of *THE JOURNAL*, Mrs. Arthur T. McCormack, Louisville, wife of the secretary of the state medical association and Judge Basil Richardson of the Court of Appeals of Kentucky. Dr. William N. Wishard, Indianapolis, will take part in the unveiling ceremony.

Increased Mortality Rate—Preliminary figures issued by the state board of health indicate that the general death rate in Kentucky in 1934 was 113 per thousand of population as compared with 108 in 1933. Infant mortality increased by almost 500 deaths, and deaths among persons 65 years old and over by more than 600. Heart disease the leading cause of death increased from 5,055 deaths in 1933 to 5,490 in 1934. The rate for pneumonia rose from 83.2 to 89.1. The department calls special attention to the rise in deaths from automobile accidents from 498 in 1933 to 625 last year. The diphtheria death rate which was noted as the highest in the United States in 1933, fell from 163 to 134, a result attributed to special efforts to have preschool children immunized. The tuberculosis rate dropped from 859 to 763, and the typhoid death rate was reduced from 12 to 11.

MAINE

Society News—Dr. George A. Tibbetts addressed the Portland Medical Club, April 2, on "Surgery in Blood Diseases."—Dr. Seth M. Milliken, New York, gave an address on "Traction in Treatment of Fractures" before the Cumberland County Medical Society, April 26.—At a meeting of the Kennebec County Medical Association, Gardiner, March 21, Drs. Howard F. Hill, Waterville, and Roland B. Moore, Portland, gave an address on "Newer Concepts in the Management of Labor."

MASSACHUSETTS

Dr. Fitz Named University Marshal—Dr. Reginald Fitz, associate professor of medicine, Harvard University Medical School, Boston, has been named university marshal in charge of the Harvard University commencement exercises in June, it is reported.

Society News—Dr. Trygve Gunderson addressed the New England Ophthalmological Society, Boston, April 16, on "Concurrent Blood for Herpes Zoster."—Dr. Ahah H. Gordon, Montreal, addressed the Harvard Medical Society, April 16, on "Clinical Aspects of Migraine."—A symposium on pneumonia

was presented at a meeting of the Essex South District Medical Society at Middleton, April 3, by Drs Frederick T Lord, Roderick Heffron and Richard H Sweet, Boston—Dr Dana W Atchley, New York, addressed the New England Heart Association, April 26, on "The Role of Peripheral Circulatory Failure in Clinical Medicine"—Dr Kendall Emerson, managing director National Tuberculosis Association New York, addressed the Massachusetts Tuberculosis League at its twenty-second annual meeting April 29, on "The Tuberculosis Program in These Changing Times"—The Obstetrical Society of Philadelphia and the obstetric societies of New York and Washington were the guests of the Boston Obstetrical Society April 12 Clinics were held at various Boston hospitals and the dinner meeting was addressed by Dr Henricus J Stander New York on "The Teaching of Obstetrics and Gynecology in the United States"—Dr Wolfgang F von Oettingen, Wilmington, Del, was a speaker on the program of a meeting devoted to occupational diseases at the annual Massachusetts Safety Conference May 6 His subject was "Toxic Vapors, Their Hazards and Control" discussed by Philip Drinker, Ch E, of the Harvard School of Public Health

MICHIGAN

Graduate Course—The Michigan State Medical Society and the University of Michigan Post Graduate Department have arranged a course in traumatic, emergency and minor surgery at the Receiving and Herman Kiefer hospitals Detroit, May 20-24

Personal—Dr Perry V Wagley has been appointed superintendent of the Pontiac State Hospital, succeeding the late Dr Edmund A Christian—Dr Burton R Corbus Grand Rapids, who has been acting secretary of the Michigan State Medical Society has resigned as counselor of the fifth district his term as acting secretary will expire in September, when Dr Clifford T Ekelund, Pontiac, will take over the duties of secretary

MISSOURI

Annual St Louis Clinics—The annual graduate course and clinical conference of the St Louis Clinics will be held in St Louis, May 20-25 The program will be clinical, covering the various branches of medicine, surgery and surgical specialties including the most recent advances in medicine and the newest methods of diagnostic technique and therapy as well as reviews of the old methods The clinic has customarily been conducted exclusively by members of the St Louis Clinics but this year the medical officers of the Seventh Corps Area, U S Army, will participate Sessions will be held at St Luke's, Missouri Baptist, St John's Jewish, St Mary's, Deaconess Firmin Desloge Barnes, DePaul and St Louis City Isolation hospitals Four evening meetings will be held at the St Louis Medical Society Building The registration fee is \$10

MONTANA

Society News—Drs Charles F Little and John R Vasko Great Falls, addressed the Deerlodge County Medical Society, Anaconda April 9 on "Nonsurgical Biliary Drainage and 'Injuries of the Spine, respectively

Personal—Dr Elmer G Balsam, Billings has been appointed president of the Montana State Board of Health and Dr Louis H Flugman Helena, vice president—Dr John C Dunn Lewistown has been named health officer of Fergus County

NEW MEXICO

State Medical Meeting in Albuquerque—The New Mexico Medical Society will hold its annual meeting in Albuquerque, May 23-25 A tentative program lists the following guest speakers

- Dr Howard C Naffziger San Francisco Surgery of Hypertensive States
- Dr Sylvan L Haas San Francisco Management of Poliomyelitis Deformities
- Dr Hermon C Bumpus Jr Pasadena Present Methods for Relieving Urinary Obstructions
- Dr Albert Soiland Los Angeles Radiation Therapy in Various Surface Conditions
- Dr Robert W Lamson Los Angeles Hay Fever Treatment
- Dr Alfred J Scott Jr Los Angeles Acute Contagious Diseases
- Dr William Warner Watkins Phoenix Ariz Traumatic Bone Lesions Without Fracture
- Dr William Paul Holbrook Tucson Ariz Present Day Conception of Arthritis
- Dr Robert C Packard Denver Fractures of the Shaft of the Femur in Children and Adults
- Dr George T Vinward Amarillo Texas Treatment of Inflammatory Conditions of the Female Pelvis
- Dr Harvey H Latson Amarillo Texas Endocrinology

NEW YORK

Dr Mahar Appointed Health Officer of Syracuse—Dr Gregory D Mahar, a member of the staff of the Syracuse department of health since 1923, was appointed health commissioner of the city, April 20, to succeed Dr George C Ruhland, who recently became health commissioner of the District of Columbia Dr Mahar is a native of Syracuse and a graduate of Syracuse University College of Medicine He entered the department of health shortly after his internship and has served principally in the bureau of communicable diseases

Personal—Dr Merle R French of the staff of the state department of health, Albany, has been appointed health commissioner of Cortland County to succeed Dr Daniel R Reilly—Dr Basil Clarendon MacLean, superintendent of Touro Infirmary New Orleans, has been appointed superintendent of Strong Memorial Hospital, Rochester, to succeed Dr Nathaniel W Faxon Dr Faxon recently resigned to go to Boston as superintendent of Massachusetts General Hospital, succeeding the late Dr George H Bigelow

Outbreak of Food Poisoning—About 750 persons in Westchester County were stricken with food poisoning April 23 and 24, as a result of eating pastries with cream filling from a bakery in White Plains Specimens of the filling examined in the laboratory of the state department of health in New York yielded colon bacilli, staphylococci and streptococci, and samples of egg yolk taken from the bakery also contained the organisms The eggs were distributed from Chicago It was estimated that many more cases occurred but were not reported to the health authorities Sixteen cases were reported in the Bronx New York where several dozen cream puffs and eclairs from the White Plains bakery were sold As soon as the epidemic was reported the bakery made every effort to recall the pastries sold and voluntarily discontinued making the cream products until cool weather The plant itself was found to be in excellent sanitary condition Dr Matthias Nicoll Jr, county health commissioner, announced that he would ask the board of health to adopt an ordinance prohibiting the sale of custard filled pastries during the summer It was reported, April 29, that federal food and drug inspectors were checking the source of the eggs

New York City

New Tumor Institute—St Clare's Hospital announces the establishment of a tumor institute opened May 15, in conjunction with the hospital A high voltage therapy machine capable of utilizing 200,000 volts has been installed along with the proper filters for correct application Radon and 400 mg of radium are available Members of organized medicine will be welcomed at all times and are especially invited to attend the hospital's weekly staff conferences

School of Midwifery to Be Closed—The Bellevue School for Midwives operated by the city since 1911, will be closed with the graduation of the present class, Dr Sigismund S Goldwater, commissioner of hospitals, announced in April Changing social conditions have made the school largely superfluous, as evidenced by the fact that only 5,000 women were delivered by midwives in 1934 as compared with 50,000 in 1914, 1,799 women held licenses to practice in New York in 1916, and the present number is 700 The average cost of confinements attended by midwives at the school is \$42.05, Commissioner Goldwater said whereas the city pays private hospitals only \$35 for confinements in charity cases

NORTH CAROLINA

Bill Introduced—S 535 proposes to repeal the laws regulating the possession and distribution of narcotic drugs and to enact what the draftsman of the bill cites as the uniform narcotic drug act The bill, however, differs from the model uniform narcotic drug act in some important particulars It omits the provisions in the model bill intended to limit the gross quantity of a habit-forming drug a person can buy in exempt preparations within a period of forty-eight hours

Society News—Dr Byrd C Willis, Rocky Mount, was elected president of the North Carolina Hospital Association at the annual joint session with the hospital associations of South Carolina and Virginia in Greensboro, April 12—Dr Sankey S Hutchinson Jr Bladenboro entertained the Bladen County Medical Society at dinner April 9 Drs Graham B Barefoot Wilmington, and Oren Moore, Charlotte, presented papers on "Electrocardiographic Findings in Diagnosis and Treatment of Heart Disease" and "Periodic Fertility in Women" respectively—Speakers who addressed the New Hanover County Medical Society, Wilmington, April 18 were Drs Silas Raymond Thompson Charlotte on "Common Uro-

logical Conditions", George Johnson, Wilmington, "Knaus's Theory of Fertility and Sterility," and Ernest S. Bulluck, Wilmington, "Fractures of the Scaphoid Bone"

NORTH DAKOTA

State Medical Meeting at Minot—The North Dakota State Medical Association will meet at Minot, May 27-28. The opening session will be held Monday evening, May 27, following the meeting of the house of delegates during the day. At this meeting Dr. Clyde E. Stackhouse, Bismarck, will give his presidential address, Dr. Leonard W. Larson, Bismarck, will discuss legislation and Dr. Harry A. Brandes, Bismarck, medical economics. Dr. Lester R. Dragstedt, Chicago, will also speak on "Experimental Studies on the Etiology of Gastric and Duodenal Ulcer." Guest speakers the second day will be

Dr. Donald C. Balfour, Rochester, Minn., "Surgery of the Gastro-Intestinal Tract"

Dr. Thomas J. Kinsella, Oak Terrace, Minn., "A Clinical Evaluation of Collapse Therapy Measures in the Treatment of Pulmonary Tuberculosis"

Dr. Henry F. Helmholz, Rochester, "Diagnosis of Acute Appendicitis in Childhood"

Dr. William H. Hengstler, St. Paul, "Head Injuries from a Neurological Standpoint"

Dr. Paul A. O'Leary, Rochester, "Established Values in the Specific and Nonspecific Treatment of Syphilis"

Dr. Roscoe C. Webb, Minneapolis, "Emergency Treatment of Fractures"

Dr. John A. Urner, Minneapolis, "Complications of Pregnancy"

Dr. William A. O'Brien, St. Paul, "Granulopenia"

The North Dakota Academy of Ophthalmology and Otolaryngology and the North Dakota Public Health Association will hold their annual meetings Monday, May 27. A golf tournament will be played Sunday, May 26, at the Minot Country Club and the annual banquet will be Tuesday evening at the country club.

OKLAHOMA

Changes in Health Officers—Recent appointments of county health officers have been announced as follows:

Dr. Benjamin B. Kies, McAlester, Pittsburg County

Dr. Benjamin F. Johnson, Fairview, Major County

Dr. Henry B. Tuston, Bokchito, Bryan County

Dr. Catherine F. T. Brydian, Ada, Pontotoc County

Dr. Henry K. Speed, Jr., Sayre, Beckham County

Dr. Edwin S. Patterson, Antlers, Pushmataha County

Dr. William P. Jenkins, Okemah, Okfuskee County

Tulsa Clinical Conference—At the spring conference of the Tulsa Clinical Society, April 17-18, clinics were held at Morningside and St. John's hospitals. There were symposiums on obstetrics, head injuries, gonococcal infections and gonorrhea, clinics on orthopedics, injuries to the back and general operative clinics by the hospital staffs. Among papers presented were the following by Tulsa physicians:

Dr. Ivo A. Nelson, "Relationship of Laboratory Medicine to Future Medical Practice"

Dr. Bernard L. Branley, "Pernicious Anemia"

Drs. Emory G. Hyatt and Delbert O. Smith, "Diverticulitis and Diverticulosis of the Gastro-Intestinal Tract"

Dr. Arthur H. Davis, "Nasal Accessory Sinus Disease"

Dr. Margaret C. Hudson, "Vaccines in the Treatment of Chronic Arthritis"

Dr. Andre B. Carney, "Benign and Malignant Tumors of the Female Breast"

Dr. Morris B. Lhevine, "Radiologic Diagnosis of Bone Tumors"

The annual golf tournament of the Tulsa County Medical Society was played Thursday afternoon at the Tulsa Country Club, followed by the annual banquet. Dr. Morris Fishbein, Chicago, editor of THE JOURNAL, spoke on "Plans for Economic Security" at the banquet, Wednesday evening, and discussed the work of the Council on Pharmacy and Chemistry at a meeting Thursday.

PENNSYLVANIA

Society News—Dr. Donald Guthrie, Sayre, addressed the Cambria County Medical Society, Johnstown, April 11, on "The Harmful Effects of Fear and Efforts Directed Toward Its Elimination from the Patient's Mind."—Dr. Edward M. Livingston, New York, addressed the Dauphin County Medical Society and the Harrisburg Academy of Medicine, April 9, on "Basic Approaches to the Diagnosis of Surgical Diseases of the Abdomen."—Dr. Jennings M. King, Jr., Pittsburgh, addressed the Fayette County Medical Society, Uniontown, April 4, on "Orthopedics in General Practice."—Dr. Isador Kaufman, Philadelphia, addressed the Lycoming County Medical Society, Williamsport, April 12, on "Physical Signs in the Early Diagnosis of Pulmonary Tuberculosis." Drs. Roy R. Snowden and John P. Griffith, Pittsburgh, conducted the semiannual clinic of the society, May 10, on fractures and gastro-intestinal disorders, respectively. Dr. Snowden also presented a paper on "Diagnosis of Carcinoma of the Stomach" and Dr. Griffith on "Management of Fractures."

Philadelphia

Survey of Tuberculosis in Indians—Dr. Esmond R. Long of the Henry Phipps Institute, University of Pennsylvania, made a special investigation of tuberculin reactions in several hundred Indian children in New Mexico and Arizona during March. Results will be studied at the institute and embodied in a report to the Office of Indian Affairs at Washington.

Statistician Hoffman Retires—Frederick L. Hoffman, LL.D., Philadelphia, consulting statistician of the Prudential Insurance Company since 1894, retired from active duty May 1, at the age of 70 years. Dr. Hoffman has written widely on medical subjects as related to insurance. In recent years he has conducted a health survey of the lead using industries, surveys of cancer in Mexico and in Europe and made a study of causes of death in various races. Dr. Hoffman is an Associate Fellow of the American Medical Association, a former president of the American Statistical Association, a director of the American Society for the Control of Cancer and the American Public Health Association, and a charter member of the National Tuberculosis Association. In 1911 Tulane University of Louisiana bestowed on him the honorary degree of doctor of laws.

Pittsburgh

Economics Meeting—The Allegheny County Medical Society held a special meeting on economics, May 10, with the following speakers: Dr. George W. Grier, Pittsburgh, "Activities of the Committee on Medical Economics"; Francis D. Tyson, Ph.D., professor of economics, University of Pittsburgh, "Health Insurance Under Medical Guidance as a Substitute for State Medicine"; and Dr. Arthur C. Christie, Washington D.C., "Economic Problems of Medicine: Is Health Insurance the Solution?"

TEXAS

New Officers of State Board—Dr. Joseph Allen Kyle, Houston, was elected president and Dr. William E. Watt, Austin, vice president of the Texas State Board of Medical Examiners at a meeting April 11. Dr. Thomas J. Crowe, Dallas, was reelected secretary. New members of the board recently appointed by the governor are Drs. Marion M. Brown, Mexico, Herschel F. Connally, Waco, and Oliver B. Kiel, Wichita Falls, and R. H. Peterson, D.O., Wichita Falls.

WISCONSIN

William Snow Miller Lecture—The eighth William Snow Miller Lecture, sponsored by Phi Beta Pi and the University of Wisconsin Medical Society, was delivered May 2 by Leslie B. Arey, Ph.D., Robert L. Rea, professor of anatomy and chairman of the division of anatomy, Northwestern University Medical School, Chicago. His subject was "Factors That Influence the Course of Wound Healing."

Society News—Drs. Enoch F. Peterson, Wauwatosa, Max J. Fox, and Myrie G. Peterman, Milwaukee, presented a symposium on scarlet fever before the Milwaukee County Medical Society, April 12. Dr. Russell L. Haden, Cleveland, delivered the first lecture in a course in laboratory methods and clinical interpretations begun March 21 under the auspices of the society.—Dr. Arthur G. Sullivan, Madison, addressed the Jefferson County Medical Society, March 21, on "Legal Pitfalls in the Practice of Medicine and Their Solution."—Dr. Edwin F. Schneiders, Madison, discussed "Early Diagnosis and Treatment of Cancer of the Breast, Cervix and Uterus" at a meeting of the Richland County Medical Society, March 14.

Health in 1934—Provisional reports of vital statistics for 1934 issued by the state board of health indicate that the death rate was 9.8 and the birth rate 16.3 per thousand of population. Diseases of the heart and cancer were the leading causes of death, with rates of 227.9 and 119 per hundred thousand, respectively, both increases over the previous year. The rate for tuberculosis, 36.5 per hundred thousand, is the lowest ever shown in the state. The influenza rate, 11.4, was the lowest since 1914, except for 1921, that for diphtheria the second lowest ever recorded, 0.84. The infant death rate was 49.9 and the maternal death rate 4.19 per thousand live births, a slight increase over those for 1933. Deaths from automobile accidents increased from 627 to 695.

ALASKA

Outbreak of Influenza—The newspapers report an outbreak of 300 cases of influenza at Point Barrow and 200 at Wainwright, with fourteen deaths up to May 7. Dr. Henry W. Greist, medical missionary at Point Barrow, reported that the situation at Point Barrow was under control. Shortage of food, coal and coffins and inadequate hospital facilities complicated the difficulties faced by Dr. Greist, who is said to be the only physician in this area.

GENERAL

Medical Bills in Congress—Changes in Status S J Res 108 has been reported to the Senate, authorizing an appropriation for the expenses of participation by the United States in the eighth International Congress of Military Medicine and Pharmacy, to be held at Brussels, Belgium, in 1935. S 2625 has been reported to the Senate, proposing to extend the facilities of the Public Health Service to seamen on government vessels not in the military or naval establishments (Rept No 600). H R 6625 has been reported to the House, conferring jurisdiction on the United States District Courts over Osage Indian drug and liquor addicts (Rept No 740). *Bill Introduced* H R 7939 introduced by Representative Fulmer, South Carolina, proposes to authorize the erection of a veterans' hospital at or near Orangeburg, S C for Negro World War veterans.

Subscription Impostor Imprisoned—Charles W Cooper, who passed himself off as a representative of the American Medical Association and collected Fellowship dues and subscriptions to *THE JOURNAL* from a number of physicians in the

south is now serving one year in prison for fraud. He is shown in the accompanying photograph. While Cooper's activities have been definitely stopped, it cannot be too strongly emphasized that all accredited representatives of the American Medical Association carry credentials signed by Dr Olin West Secretary and General Manager. A safe rule is to pay no money to strangers.

Charles Cooper is an

affable appearing, businesslike young man and apparently was clever enough to sidestep the matter of credentials when calling on physicians. Any genuine representative of the American Medical Association will gladly produce credentials when asked to do so.

Society News—The American Association for the Study of Goiter will hold its annual meeting in Salt Lake City, June 24-26.—The Association for Research in Ophthalmology will hold its annual meeting in Atlantic City at the Marlborough-Blenheim, June 11. Among others, the following will deliver addresses: Drs Samuel Hanford McKee, Montreal, Canada, on "A Study of the Pneumococcus Group from the Inflamed Conjunctiva and Lacrimal Sac." William M James, St Louis, "Lysozyme Content of Tears." Theodore L Terry and Juanita P Johns, Boston, "Uveal Sarcoma (Malignant Melanoma)," and Adelbert Ames Jr, LL B, Hanover, N H, "Aniseikonia—A Factor in the Function of Vision."—Dr Charles F Craig New Orleans, was elected president of the American Academy of Tropical Medicine at a meeting in New York, April 16, and Dr Richard P Strong Boston vice president. Dr Earl B McKinley Washington D C was reelected secretary. It was decided to hold the annual meetings hereafter in connection with the meetings of the American Society of Tropical Medicine.

News of Epidemics—The most extensive epidemics of measles in recent years are being reported in many communities. Erie, Pa., had 247 cases of the three-day type of measles reported in the week of April 13-20, 523 cases had been reported in March. The health officer of Williamsport, Pa., reported that 470 homes were quarantined for measles, April 5. About 600 children had had the disease in Easton Pa., it was reported, April 13. The state of Michigan had 28,000 cases, 2,775 in Detroit, April 13 according to a newspaper account. More than 200 students at Williams College, Williamstown, Mass. a fourth of the student body were reported to be ill with German measles May 3. More than 700 children had been affected in an epidemic of measles in Eveleth Minn., it was said April 18. In Chicago 1,407 cases were reported in the week of May 1.—Schools closed for the year in Avilla, Ind. April 9 one month early in an effort to check an epidemic of scarlet fever. In Milwaukee where scarlet fever has been epidemic for several months active cases were reduced to 852, it was reported April 29. Schools were closed during April because of scarlet fever in Libertyville Ill. Tharpstown, Pa., and Urbana Ohio newspapers reported. In Minneapolis all children under 7 were quarantined from April 17 to May 5 to curtail the spread of scarlet fever.—Grade schools in Minerva,

Ohio, were closed April 8, when two boys were stricken with meningitis, one died. There have been 109 cases of meningitis in Cincinnati since the first of the year, eighteen cases were in the Cincinnati General Hospital April 10.

Conference on Rheumatic Diseases—The second annual meeting and the fourth conference of the American Association for the Study and Control of Rheumatic Diseases will be held at Atlantic City, June 10 at the Marlborough-Blenheim, under the presidency of Dr Ernest E Irons, Chicago. The morning will be devoted to a consideration of chronic arthritis and the afternoon to rheumatic fever. The following physicians will participate:

Russell L Haden and Robert A Warren, Cleveland Accelerating Factors in Chronic Degenerative Arthritis.
John S Coulter Chicago Home Treatment of Chronic Arthritis by Physiotherapy.
Russell L Cecil New York, Malarial Therapy in Rheumatoid Arthritis.
Philip S Hench Rochester Minn. Results of Fever Therapy for Gonorrheal Arthritis Chronic Infectious (Atrophic) Arthritis and Other Forms of Rheumatism.
Albert B Ferguson Haig H Kasabach and George Douglas L Taylor New York Further Studies on the Roentgenologic Findings in Various Forms of Chronic Arthritis.
Byron D Bowen and Louis Maxwell Lockie Buffalo Chronic Atrophic Arthritis Effect of High Carbohydrate Diet and Insulin on Symptoms and Respiratory Metabolism.
Edward F Hartung New York, Treatment of Rheumatoid Arthritis with Leukocyte Cream.
Readie Garfield Snyder Cornelius H Traeger and Carl A Zoll New York Use of Cinechophen and Its Derivatives in the Treatment of Chronic Arthritis.
Homer F Swift New York The Nature of Rheumatic Fever.
Morse J Shapiro Minneapolis, The Natural History of Childhood Rheumatism in Minnesota.
Martin H Dawson and Terence L Tyson Jr New York Relationship Between Rheumatic Fever and Rheumatoid Arthritis.
Currier McEwen New York Cytologic Studies on Subcutaneous Nodules in Rheumatic Fever and Rheumatoid Arthritis.
Edward Sterling Nichol Miami Fla The Geographical Distribution of Rheumatic Fever and Rheumatic Heart Disease in the United States.
James F Rinehart, San Francisco Studies Relating to Vitamin C Deficiency in Rheumatic Fever.
Albert D Kaiser Rochester N Y Influence of the Tonsils on Rheumatic Infection in Children.
Hugh McCulloch St. Louis Institutional Provisions for the Care of the Rheumatic Child.
Lucy Du Bois Porter Sutton and Katharine G Dodge New York Fever Therapy in Chorea.

FOREIGN

Congress on Medical History—The tenth International Congress of the History of Medicine will be held in Madrid, September 23-29, under the presidency of Prof Gregor Marañon. Subjects for discussion will be Arab medicine in Spain, medicine in America during its discovery and colonization, and medical folklore in civilized countries. All who wish to collaborate are asked to send abstracts of their communications before June 1 to the office of the secretary of the congress, Palacio de la Academia Nacional de Medicina, Calle de Arieta, 12, Madrid. An exhibit of rare and curious books by Spanish and Spanish-American authors is being organized.

Scholarships at Forlanini Institute—The Italian Fascist National Federation Against Tuberculosis has placed at the disposal of the International Union Against Tuberculosis six scholarships for foreign medical practitioners at the Carlo Forlanini Institute in Rome. The scholarships, which have a value of 3,000 lire plus board and lodging will preferably be awarded to young physicians already familiar with problems of tuberculosis. The period of study will be from November 15 to July 15, 1936 the academic year. Candidates from the United States must apply through the National Tuberculosis Association, 50 West Fiftieth Street, New York, before June 1.

International Neurologic Congress—Plans for the second International Neurological Congress in London July 29-August 2, have been announced. The American delegation will leave New York on the S S *Manhattan* July 17, to arrive in London July 23. According to the program, Drs Stanley Cobb, Boston, and Wilder G Penfield, Montreal, will take part in a symposium on the epilepsies, Dr Lewis H Weed, Baltimore, in one on the physiology and pathology of the cerebrospinal fluid, and Dr Harvey Cushing, New Haven, Conn., in one on the hypothalamus and cerebral representation of the autonomic system. Sessions for miscellaneous papers will be held in addition to the symposiums. The triennial Hughlings Jackson Memorial Lecture will be presented by Prof Otfried Foerster, professor of neurology, University of Breslau, Friday evening August 2. Social affairs will include receptions given by the Royal College of Physicians, the Royal College of Surgeons and the section of neurology of the Royal Society of Medicine. Dr Henry Alsop Riley, 117 East Seventy-Second Street, New York, is secretary for the United States.

Effect of Unemployment on Health Insurance Finance

At the annual dinner of the National Federation of Employees' Approved Societies, Mr. Edgar Hackforth, deputy controller of the insurance department in the ministry of health, said that employers in this country were not so severely handicapped as they were some years ago by their expenditure on social services, because some of their foreign competitors had followed their example by introducing social schemes. The effect of unemployment on the health insurance scheme was their most important problem and they had not yet solved it. Unemployment diminishes contributions and increases expenditures on benefits. At the end of the year, if the law remained as it was, a considerable number of insured persons would find themselves losing not only all their health insurance title to benefit but also their title to pensions simply because they happened to have a prolonged period of unemployment. As regards loss of pension rights something like 200,000 persons might be affected and as regards health insurance the number would be much higher. He was referring to old age pensions and does not mean that these persons will lose them entirely, but they lose the right of the pension beginning at 65 which insured persons have, while for others the pension begins at 70. There were over 5,000,000 insured persons in this country who, because they had been unemployed for more than four weeks in the year, were in the position of having their health insurance benefit subjected to a reduction in the following year unless something special was done for them. The department had done all that it could under the finances of the present scheme but it had to face the problem whether it was possible to return to the basis of the act of 1928, by which all the arrears due to unemployment could be excused. That was a difficult problem. It was satisfactory that 1934 did show a marked improvement in the general finance of working the insurance. Employment improved and was accompanied by a material fall in expenditure on sickness and disablement benefits. At the annual meeting of the federation, the president asked why there should not be included in the benefits to which an insured person is entitled under the unemployment insurance acts some provision against his liability for the contribution required to keep him in benefit for health and pension insurance. This arrangement had worked for many years in Germany, where 170,000 had dropped completely out of insurance and become a charge on public assistance during ill health.

British Memorial to Madame Curie

A banquet in support of a British memorial to Madame Curie was held in London. The purpose was to raise \$250,000 for the endowment and extension of the Marie Curie Hospital of London. Mr. Neville Chamberlain, who took the chair, said that he had been asked to do so because of his long association with the ministry of health. He paid a humble tribute to a very great woman, a most original and fertile investigator, and one of the great benefactors of the human race. To the toast to her memory her daughter, Miss Eva Curie, a well known musician, responded. She said that her mother often said that "in science we should be interested in things, not persons." She meant that her own person was of no importance compared with the things to which she devoted her life. A discovery made by any scientist gave her as sincere joy as a discovery of her own. The burden of celebrity overwhelmed her, and at the end of her life she still said, "I am nothing but a student." All the passion that she scorned to devote to seeking honors she devoted to helping those in need of her. During the war

she drove a ray car along the French and Belgian fronts and carried out roentgen examinations of thousands of wounded, her postwar activities were devoted to the practical development of radium therapy. The physicist Sir William Bragg spoke of the eminence of Madame Curie in physics and the difficulty and hardship of the conditions under which her discoveries were made—in a building with an asphalt floor and a glass roof, by no means proof against the rain, a hothouse in summer, and in winter scarcely warmed by a single stove, with furniture consisting of old tables on which the specimens were deposited. But, she wrote, "I shall never forget the ravishing joy we used to have on coming home at night when we saw the faintly luminous shapes of the products of our toil."

Pay Patients in the Voluntary Hospitals

A bill to enable hospitals to provide pay beds, provided it is not done at the expense of ordinary beds, was read a second time in the house of lords. Patients in the pay beds would be those whom a hospital almoner would not usually accept in the ordinary wards but who could not afford the cost of private treatment in their homes and urgently required the assistance of a hospital with all its specialist treatment. Such patients are sometimes called the "black coated poor." Some voluntary hospitals have already done this but they have had to obtain a private act of parliament which costs at least \$2,500. Some misgiving was expressed by the labor party in the house as to whether the bill would cut down the services for poor people as the hospitals had long waiting lists. The labor party was dissatisfied with the hospital system and wanted all the hospitals to be taken over by the municipalities publicly controlled for the free treatment of all who needed it. It was not right that the great health services which the hospitals provided should be supported by costly banquets, balls, braziers, fetes and flag days and inadequately supported at that. For the government Viscount Hailsham said that a case was made out of the desirability of having some beds available for the class that was willing to make some payment toward the expense of treatment but was unable to afford the fees of a nursing home. But there should be safeguards to ensure that the funds settled on it for the benefit of the sick poor were not diverted for any other purpose.

Overcrowding of the Medical Profession

During 1934 the names added to the British Medical Register amounted to 1,664, and 898 were removed by death and a small number by other causes giving a net increase of 755, which brings the total number on the register up to 57,496. This figure may be compared with 44,761 in 1920 and 40,483 in 1910. In 1934 the number of medical students who registered was 2,350, a number without parallel save for the exceptional years of 1919 and 1920 following the war. Thus Great Britain is no exception to the overcrowding of the medical profession reported in other European countries, though this has not yet attracted attention here. Complaint of overcrowding has been made also in Australia. No cause has so far been assigned for the increase in Great Britain beyond a suggestion that there has been a considerable expansion in recent years of the public medical services. A more probable and a regrettable cause is the great difficulty of the rising generation in the class from which medical students come in obtaining employment of any kind in this period of unprecedented industrial depression.

Objections to the Sterilization of Defectives

In an address to the Manchester and Salford branch of the National Council of Women Dr. Charles Rankin, a psychiatrist, urged the need of caution before coming to conclusions on the sterilization of mental defectives. The recent report of the committee appointed by the government had recommended the legalization of voluntary sterilization in persons suffering

from hereditary forms of mental disorder or defect or from grave hereditary forms of physical debility. Dr Rankin doubted whether these were scientific recommendations. Half the mental deficiency was due not to hereditary but to environmental causes, yet on the latter the committee had little to say. It admitted the need for research into hereditary factors in mental and physical disability. He believed that of no mental disorder was the exact nature of the inheritance known. All that was known was that inheritance proceeded through mendelian laws. No doubt heredity was a factor, but the question was as to its assessment compared with racial poisons, such as tuberculosis, syphilis and alcohol. Only a small proportion of defectives had definitely certifiable parents. He also objected to sterilization on moral grounds as it would encourage irresponsibility in sex behavior and the propagation of venereal disease. Against these arguments it could be urged that although the part played by heredity in mental deficiency cannot at present be exactly assessed, it cannot be questioned that sterilization of mental defectives would do something to reduce the incidence of the condition in our population.

The Primary Tuberculous Focus in Adults

An examination of all first year students at the University of Strasbourg was begun in 1929 by Vauchier, Strauss and Schneegans. It comprises a complete physical examination including roentgenoscopy and, in suggestive cases, films of the chest, together with an examination of the nose, throat, ear and teeth. The observations in regard to tuberculosis were the subject of a paper read at the Dec. 14, 1934, meeting of the Société médicale des hôpitaux de Paris. Thirty-five cases of active pulmonary tuberculosis were discovered in the examination of 1,343 students. Twenty-five of the thirty-five students were unaware of the presence of any pulmonary lesion.

During 1931-1932 skin reactions were used in 232 cases of which sixty were negative but of which three became positive shortly afterward. Another cutaneous and then an intradermal test was made of forty-one students whose primary reaction had been negative. Of these forty-one the later tests were positive in eleven, negative in twenty-five and doubtful in five. Emphasis is laid on this observation which teaches that, if one had been content with a single skin test, more than 30 per cent would have been found negative. If a cutaneous test is negative, a second, preferably an intradermal test should be made later.

Five cases were reported in which the skin reaction was negative. In the first student, a girl of 18, the skin reaction was negative in 1932 but she showed evidences of a serofibrinous pleuritic exudate and a large lymph node at the hilus of the right lung as the first sign of tuberculosis. In a second case, two skin reactions at intervals of fifteen days were negative. This patient was serving as an extern in a tuberculosis ward. Four months later, signs of a left dry pleurisy appeared. Roentgenography revealed a bilateral adenopathy in both pulmonary hili. In the third observation, two skin tests and one intradermal reaction were negative in a girl student in 1932. A year later, when clinical work was begun, fatigue and loss of weight led to a roentgenographic examination, which revealed discrete pulmonary nodular lesions in both apices. Two other cases were reported in which the tuberculous infection was apparently primary in adolescence with involvement of the hilar lymph nodes as the first evidence.

In the majority of cases there is absence of any clinical symptom of tuberculous infection. In several students the skin reaction became positive as soon as ward work was begun but even in these cases there were no clinical signs. In some

apparently primary cases in young people the infection begins as an acute caseating lesion. Another clinical form is that in which at the onset there is a more or less prolonged febrile period without any accompanying clinical manifestation. This is the typhoid-like form of tuberculous infection, which is often diagnosed as influenza or intestinal infection. This was true of three of the five cases reported in which, a little later, evidence of lymph node involvement (at the hilus) or a dry or exudative form of pleuritis appeared.

Nico in his thesis has reviewed the literature of primary tuberculous infection and has found that a serofibrinous pleuritic exudate is commonly the first clinical sign that attracts attention. Such a pleurisy is of course secondary. Skin reactions should be regularly employed in young students and soldiers, especially in medical students and nurses. When the skin reaction is negative, the individuals should be cautioned against exposing themselves to cases of pulmonary tuberculosis. Students who have a negative skin reaction should be vaccinated with the BCG vaccine and clinical work should not be permitted until five weeks later.

Rist, in the discussion, stated that his experience with a large number of students confirms that of Vaucher and his associates and that of foreign clinicians, especially Myers of the University of Minnesota. Those students who have a negative skin reaction should be kept under observation. Every student in the Paris medical school is obliged to have such a skin test made at the time of matriculation. It would be well to add a roentgenographic examination, such as is carried out at Strasbourg.

Methods of Resuscitation in Asphyxia

At the Dec. 4, 1934, meeting of the Academy of Medicine, Nicloux and Legendre stated that only too often the one who is trying to save a life becomes a victim. A drowning person ought to be approached only from behind and held by the back of the head. The first duty in cases of asphyxia is to try to ventilate the room before any attempt is made to remove the asphyxiated person. In the case of ditches or mine galleries the life saver should never enter unless a rope keeps him in touch with some one in the free air so that he can be pulled out. In trying to remove any one from high tension wires one is interfered with by wet soil, shoes or feet; hence one should try to find a nonconductor in the shape of a board, chair or stool and to use only one hand in detaching the victim.

In France, two methods of artificial respiration, the Sylvester (raising the arms at regular intervals) and the Laborde (rhythmic tongue traction) have been abandoned in favor of the Schafer method. An apparatus devised by Dr. Paris acts automatically to carry out the Schafer method and is extensively used in Paris.

Artificial respiration must be kept up, whether by the Schafer method or by some such apparatus, for a long time, even for hours. The only adjuvants to artificial respiration are maintenance of the body heat of the victim (especially in cases of drowning) and the inhalation of oxygen.

Carbon dioxide is not of much help in the dissociation of the carboxyhemoglobin in cases of gas asphyxia, whereas oxygen will be of assistance.

At the January 22 meeting of the Academy of Medicine, Cot and his associates discussed the same subject. The Schafer method has been employed exclusively since 1924 by the Paris fire department. The hands are applied at the base of the thorax, the victim lying face downward. As much pressure as possible is applied to provoke expiration, no pressure being used during inspiration. The theory of this method (Schafer) is to stimulate the diaphragmatic reflex. It is far less fatiguing to apply than the Sylvester or the Laborde method. Pulmotors do more harm than good. The insufflation of air under pressure only increases the already existing pulmonary congestion.

and edema Brickley is quoted as having found tears and hemorrhages following the use of this method in animals

The only forms of apparatus that are of help apply force externally to stimulate respiration. The authors have devised such an apparatus, which is designed to imitate the movements employed in the Schafer method. In 1934, 75 per cent of the victims of asphyxia from illuminating gas and charcoal fumes were resuscitated, but only 60.2 per cent of the victims of drowning. The Cot apparatus was the only method of artificial respiration employed in the last eight months of 1934.

Roentgenographic Diagnosis and Treatment of Intussusception

In a recent article Poulhiquen of Brest states that until lately the diagnosis of intussusception in infants was based on the triad colics, vomiting and bloody stools. At present the most valuable method of diagnosis and occasionally of reduction, is the barium sulphate enema under fluoroscopic control. This should be employed as early as possible and, if it reveals inability to reduce the intussusception, operative treatment must follow immediately. The barium enema may occasionally be successful in the reduction of the invagination, 200 Gm of barium sulphate to a liter (quart) of water suffices and one can safely raise the irrigator to a height of 4 feet (120 cm) or even a few inches higher in early cases. With the exception of the left colocolic and transverse colon forms, the mass can be easily pushed over to the right iliac fossa, where one has an opportunity to observe whether the barium enema enters the ileum freely, which is the sole criterion of a successful nonoperative reduction.

If only a few irregular shadows or streaks are seen in the ileum, the attempt at reduction by the barium enema must be regarded as having been unsuccessful. If, however, the barium has passed in large amounts into the lower ileum and one can no longer feel the invagination, reduction has been successful. It is necessary to keep in mind the possibility of a double invagination, as two cases recently reported by Bloch and Duroselle show. The only criticisms against nonoperative reduction under fluoroscopic control are that one cannot prevent a recurrence by fixation of the intestine. The indication for such an operation is rarely present and it should be employed only in recurrent cases. Another objection is that there may be an accompanying acute appendicitis, but this is rare, especially in the first year of life. A case of rupture of the intestine has been reported by Fèvre, but this was in an advanced, inoperable case. The most important argument against nonoperative reduction is, then, the danger of recurrence. Poulhiquen has had a large experience and has observed only one such case. Reduction by a barium enema will be successful in at least 60 per cent of the cases. The ileocolic form is the least favorable for nonoperative reduction. If vomiting or the inability to pass flatus or feces persists, the roentgenoscopic examination can be repeated in a few hours and an operation performed at once. A right lateral incision is to be preferred and every effort should be made to reduce the invagination because the prognosis is very unfavorable in cases in which resection is unavoidable.

Search for Bacteriophage in Water Supplies

At a recent meeting of the Academy of Medicine Dr. M. F. Dienert discussed the necessity of a routine examination of sources of water supply and discharge, for the presence of bacteriophages. The excreta of patients suffering from any form of intestinal infection always contain a bacteriophage. This ultravirus is transported into the sewers and from them into the adjacent rivers. Gildemeister and Watanabe have found an increase of bacteriophage in the river Spree (Berlin) five days after a rainfall. Dienert has observed an increase in the amount of the anti-Eberth bacillus or antiparatyphoid A or B

bacteriophage in the Seine, into which the waste of Paris drains, whenever there had been patients either in the acute stage of typhoid or convalescing from an attack. The bacteriophage remains viable much longer, six months for example, in water or in the soil, than the typhoid or paratyphoid organisms. For this reason one ought systematically to search for bacteriophage in the waters into which a city discharges its waste, in order to trace cases of typhoid which have either not been reported or in which the excreta have been inadequately disinfected.

BERLIN

(From Our Regular Correspondent)

March 11, 1935

The Mortality from Various Diseases

In 1934 the mortality from the infectious diseases of childhood was 29.4 per cent greater than in the previous year. As in 1933, the mortality rates for measles, scarlet fever and whooping cough were highest in the first quarter, and for diphtheria in the last quarter.

The number of infant deaths from syphilis in 1934 was 0.36 per thousand, which denotes a further decrease over 1933 (0.45 per thousand). This mortality was greatest in the cities on the Rhine and the Main, and in the seaports. Because of the sustained high summer temperatures, the infant deaths from intestinal catarrh increased (from 4.8 to 5.1).

Table 1 shows the number of deaths in 1934 from the diseases of the more advanced years, and the deaths for 10,000 of population during the period 1930-1934.

TABLE 1—Deaths in 1934 from Diseases of Advanced Years,
Deaths for 10,000 of Population, 1930-1934

	Total Deaths in 1934	Deaths for 10 000 of Population in				
		1930	1931	1932	1933	1934
Cancer and other malignant growths	20 427	13.8	14.5	14.5	14.7	14.9
Apoplexy	18 791	8.0	8.3	8.6	9.2	9.5
Diabetes	3,840		1.7	1.9	2.0	1.9
Senile debility	10 155	4.6	5.1	5.3	5.6	5.1

It appears that the deaths from malignant growths and from apoplexy show an increase, but no greater increase than the increased representation of the older age groups would lead one to expect. The decreased mortality from senile debility is doubtless due to the fact that in 1934 there was no pronounced influenza epidemic such as occurred in 1933.

Table 2 shows the number of deaths in 1934 from other important diseases.

TABLE 2—Deaths in 1934 from Other Important Diseases,
Deaths for 10,000 of Population 1930-1934

	Total Deaths in 1934	Deaths for 10 000 of Population in				
		1930	1931	1932	1933	1934
Cardiac diseases	27 490	13.3	12.6	13.0	14.0	13.0
Tuberculosis	14 248	8.1	8.1	7.5	7.5	7.7
Pneumonia	13 078	7.1	7.5	6.3	7.0	6.6
Nephritis	4 033		2.2	2.1	2.0	2.0
Bronchitis	2 405		1.6	1.4	1.6	1.2
Influenza	1 624	0.7	1.8	0.8	2.0	0.8
Typhoid	148	0.09	0.06	0.08	0.07	0.07
Cerebrospinal meningitis	122	0.08	0.06	0.06	0.06	0.06
Encephalitis	63	0.03	0.04	0.02	0.02	0.03

The number of deaths from puerperal fever showed, because of the greatly increased number of births, the greatest increase of any cause of death (39.7 per cent higher than in 1933), whereas the other accidents of pregnancy and of childbirth showed a much smaller increase (8.7 per cent). The deaths from puerperal fever following miscarriage show a marked decrease, namely, 13.0 per cent.

The deaths due to violence and accidents during the period 1929-1934 are outlined in table 3

TABLE 3—Deaths Due to Violence and Accidents, 1929-1934

	1929	1930	1931	1932	1933	1934	1934 in Percentage Relation to 1933
Suicide	5 868	6,207	6,346	6 497	6,335	6 032	95.2
Murder and manslaughter	295	358	360	305	382	273	71.5
Accidents	6 436	6,314	5 028	5,723	5 025	5 560	111.0

Non-Aryans in Panel Practice

The federal minister of labor, who is competent to answer all questions pertaining to the health insurance societies, stated recently, in response to an inquiry, that there were no objections to the preparation of lists of panel physicians, differentiated according to Aryans and non-Aryans for the use of the *krankenkassen*. It was well known that the *krankenkassen* had such lists, and there may be said to be need for them in order that the insured may be given information in response to inquiries concerning the racial origin of a panel physician. It was not important whether the *krankenkassen* prepared such lists or whether they secured them from the *Kassenärztliche Vereinigung Deutschlands*. This attitude is significant for forming a judgment in regard to the situation, for the non-Aryan physicians admitted to panel practice are either those who were admitted before the war or who were admitted because they fought at the front. It was for the benefit of the latter class that the special privileges were created.

In the recent regulations for admission of students to medical examinations is found this new provision: "Admission to the examinations and the granting of a license to practice presuppose the furnishing of proof of Aryan origin (birth certificate of the candidate, birth certificates and marriage licenses of the parents and of the grandparents on both sides)." The same requirements apply to candidates for the diploma of dentist. This corresponds to the attitude that the Berlin rector announced some months ago (*THE JOURNAL*, March 3, 1934, p. 710).

Admission to Dental Practice

Little has been heard of late about the question of extending the privileges and the medical activities of the nature cure doctors. If any progress in this direction has been made, it has not been announced. Doubtless the opposition has proved to be greater than was anticipated. On the other hand, an old demand of the dental technicians has been granted. In place of the term dental technician, which in German usage plainly designates the limited training of such persons in comparison with the academically trained dental physicians, the federal minister of labor has substituted the term 'dentist'. At the Berlin *Lehrinstitut für Dentisten* persons without means are supplied with prostheses free of charge. April 1 there will be opened in Düsseldorf one of the seven dental schools to be created throughout the reich, and it promises to be the most modern school for dental technicians in Germany. The director will be a dental technician or 'dentist' and not a *saluarzt* or dental physician. Both dental physicians and dental technicians must be entered in a register before they are admitted to practice. According to a recent decree an applicant will not be admitted unless he and his wife are of Aryan origin. The previous exception according to which front line combatants, including the fathers and sons of persons who died in the World War were admitted even though of non Aryan origin has been abolished. This makes the application of the regulations much more severe and works a hardship on the sons of men who died in the war, who, relying on the previous exceptional privilege, have already partially completed their course in dentistry. Furthermore, a license to practice already granted will be with-

drawn if an Aryan dental physician or 'dentist' admitted to panel practice marries a woman of non-Aryan origin or has married such a woman since July 1, 1933.

A system of relief, organized by the dental physicians and supported in part by the federal government, has been created in the sections of Röhn and Spessart, two high plateau regions of Germany that have suffered severely from the economic crisis. Four Berlin dental physicians with four woman assistants have treated, during the past few months, more than 1,500 children gratis in this area. It is planned to give dental aid to about 8,000 children.

Boric Acid in Remedies for Obesity

The federal bureau of health has called attention to obesity remedies containing boric acid and borax, which are injurious to health. In recent years obesity remedies containing boric acid free or in combination with other substances, have been put on the market. Boric acid and borax, if taken in quantities of more than a fraction of a gram, are not harmless substances. The public should inquire whether the preparations contain any boric acid.

Similar observations in Denmark led to the recent order that obesity remedies may not contain boric acid or its salts.

A Central Cancer Institute

In the Rudolf Virchow-Krankenhaus in Berlin a central cancer institute that is to serve all northern Germany is to be created. It will be both a therapeutic and a research center. As the first step, a large committee has been appointed, on which, among others, the whole Berlin faculty of medicine will serve, Professor Sauerbruch being the chairman. For this institute, which is to be directed by Professors Cramer and Hintze, a suite of rooms with 300 beds, in the aforementioned hospital, has been selected.

BUENOS AIRES

March 1, 1935

Cancerigenic Action of Sunlight

Dr. A. H. Roffo has succeeded in producing cutaneous cancer in the face and ears of white rats by repeated exposure of the animals to sunlight. From these results of experiments, he believes that sunlight baths have a cancerigenic action. His statement has encountered many objections, because 1. A reasonable and well controlled exposure of children and young adults to sunlight produces a beneficial action on their health. 2. Sunlight is helpful in the treatment of tuberculosis of the bone and of surgical tuberculosis. 3. Cutaneous cancer does not develop frequently in bovine, equine and other animals that are exposed to sunlight the year round.

Quinoa Seeds as Food

The seeds of quinoa (*Chenopodium quinoa*) were used as a food by the Incas and are still used as such in Peru, Bolivia and the northern regions of Argentina. Dr. P. Mazzocco made a study of their alimentary value and found that the protein content of quinoa seeds is sufficient. They contain also vitamin B and are an excellent food if associated with cereals that contain vitamins A, C and D, the content of which is insufficient in quinoa seeds.

Early Diagnosis of Cancer

Special departments for the diagnosis of tumor tissues, removed by a biopsy, have been organized or are in organization in several municipal hospitals of Buenos Aires, having as an aim the early diagnosis of cancer and early treatment. Drs. Mosto and Brachetto-Brian are directors of the departments in the Rawson and Durand hospitals, respectively.

Pan-American Health Conference

The ninth Pan American Health Conference was held at Buenos Aires Nov 12-22, 1934, by representatives from all countries of North and South America. All the suggestions made by the North American delegation, formed by Drs Cumming, Lloyd Long and Emerson met with the general approval of the attendants. The following motions were made: Adoption of the international health convention for air navigation (The Hague) ratification of the resolutions taken at the International Health Convention held in Paris in 1926, a decennial census of the population unification of the departments of public beneficence and welfare, both public and private, under one authority organization of aviation, continuation of the studies on typhus and yellow fever. Dr F. L. Soper of the Rockefeller Foundation read a paper on yellow fever in South America. He proved that there are foci of endemic yellow fever in certain regions of South America where there are no mosquitoes and that the transmitting agent is unknown in these cases. In connection with his article the following motions were made: 1 To carry on studies on the protective power of antiserum. 2 To investigate the frequency of yellow fever by the performance of microscopic studies of the liver of cadavers of persons who died within ten days of the onset of a febrile disease. In these cases the pieces of liver should be taken by biopsy with a special viscerotome. 3 The organization of antilarval work in ports and air ports where the presence of *Stegomyia* has been established. 4 Preventive vaccination of those who are in possible contact with infected cases. 5 Organization of special laboratories for work on yellow fever. Cooperation of the pharmacopoeial committees of North and South American countries tending to the establishment of a unified pharmacopoeia for both continents was advised. Resolutions to intensify the campaigns against tuberculosis, uncinariasis, leprosy, malaria, plague, brucelliosis, venereal diseases, alcoholism and narcotism were adopted.

Personal Items

Dr Alfredo Sordelli, director of the Instituto bacteriologico nacional, has been appointed a member of the Committee of Biologic Standardization of the Society of the Nations and a corresponding member of the Societe de biologie of Paris.

Dr B. A. Houssay has been appointed a corresponding member of the Academie de medecine of Paris, an honorary member of the Academia de medicina of Madrid, and an honorary fellow of the Royal Society of Edinburgh.

Dr J. Bacigalupo has been appointed a corresponding member of the Societe de pathologie exotique of Paris.

Dr Avelino Gutierrez has been appointed an honorary member of the Academia de medicina of Madrid.

Dr R. Araya de Rosario was awarded the Santour prize by the Academie de medecine of Paris for his work on ovulation and menstruation. Dr Araya states in his article that there is no relation between the phenomena of ovulation and menstruation.

Dr J. C. Ahumada has been appointed professor of gynecology at the Faculty of Medicine of Buenos Aires.

Drs Foz and Baraldi have been appointed professors of psychiatrics and surgery, respectively, at the Faculty of Medicine of Rosario.

Dr Oscar Orias has been appointed full time professor of physiology at the Faculty of Medicine of Cordoba.

Drs F. Bottazzi of Naples, L. Brauer of Hamburg, L. Binet of Paris and C. Monge de Lima were appointed honorary academicians to the Academia Nacional de Medicina of Buenos Aires. Drs L. Surraco of Montevideo and Garcia Otero of Montevideo were appointed correspondent academicians of the same society.

Dr R. Bullrich has been appointed honorary professor of the Faculty of Medicine of Montevideo.

March 6 1935

The Congress of Neurology and Psychiatry

The twelfth Congress belge de neurologie et de psychiatrie was to have been held in Belgium, but the Netherlands Neurologic and Psychiatric Society conceived the idea of merging the congresses of the two societies and of holding the joint session this year in Amsterdam.

The first paper dealt with "The Neuro-Anemias" and was presented by Professor Van Geuchten. The neuro-anemic syndrome is the disorder that is encountered most frequently after tabes and multiple sclerosis. The characteristic lesion of neuro anemia is the vacuolar degeneration of the white substance. The formation of vacuoles is due to the combined involvement of the axis cylinder and the myelin sheath. The lesion is not pathognomonic of the neuro anemic syndrome. The localization of the lesions in the nervous system has not been fully explained; possibly it is conditioned by the vascular topography. The gray substance is less changed but does not completely escape involvement (chromolysis, masses of pigment in the cells, and the like). Pernicious anemia and the neuro-anemic syndromes are deficiency disorders. Normally the factor that prevents pernicious anemia is found in the gastric juice. In case of an insufficiency of this factor, grave symptoms arise in the organism which, it is believed, are attributable to disturbance of lipid metabolism.

Among the other communications an experimental contribution on The Clinical Characters of Parkinsonian Trembling may be mentioned, by Rene Nissen and Rene Dellaert. Their results may be summarized thus: A distinction must be made between the results secured in senile patients and those furnished by encephalitic patients. In the former the mode of reaction is almost constant whereas in the latter modification in the trembling varies from case to case. In the same senile patients the trembling increases in the nonactive members. The results secured in senile patients through the tests of mental effort and of emotions likewise confirm the conceptions of Kleist, Jong and Froment in that one accords to these states a significance opposed to that of repose. As regards encephalitic patients, in view of the difference in the reactions in various cases, neither of the two general conceptions can be maintained with respect to either the member in motion or the symmetrical member. What has just been said in regard to encephalitic patients is particularly frank and striking in arteriosclerotic parkinsonism. Two other facts to be noted are: (a) the frequent and sometimes very marked dyschromism between the hand and the foot, in both the senile and the encephalitic patients; (b) acceleration of the trembling which constitutes an almost constant reaction under the influence of the different factors considered.

Mode of Infection in Weil's Disease

It is generally recognized that there is more than one way in which *Leptospira icterohaemorrhagiae* gains entrance to the human organism from water: through the skin (particularly if the skin is broken) or through the mucosae. In the *Nederlandsch Tijdschrift voor Geneeskunde* Dr. Van Thiel emphasizes the significance of infection through drinking water, particularly through the nasal and buccal mucosae.

The author performed a series of experiments on the guinea pig and the rat, the results of which he reported in detail. Although the possibility of an infection by mouth was confirmed, several million pathogenic organisms may be swallowed by the animal without any infection developing. Infection is brought about much more easily through the nasal mucosae, the conjunctivae or the lacrimal canal. The author concludes from this fact that the water snuffed up the nose by swimmers constitutes an especially grave danger.

MOSCOW

April 2, 1935

Report on the Public Health

At the sixteenth All Russian Congress of Soviets in Moscow, January 6-16, a report of the People's Commissariat for Health was read. The following data presented before the congress shows the progress in the field of public health.

Changes Between 1913 and 1934

	1913	1934
Number of hospitals	780	1,740
Number of hospital beds*	103,000	318,000
Obstetric beds	5,500	82,000
Health points in industrial plants*	3,300†	4,300
Polyclinics	880	2,600
Tuberculosis dispensaries	43	410
Physicians	About 15,000	53,000

* Except beds for mental patients

† Health points in 1913 were given by first aid ambulance doctors by physicians' assistants. Now they represent well equipped polyclinics in plants and manufacturing

Changes Between 1928-1929 and 1934

	1928-1929	1934
Number of public nurseries in towns	772	3,330
Number of places in permanent country public nurseries	7,500	3,000,000
Number of places in summer country public nurseries	115,000	3,200,000
Number of workers who visited health resorts and spas	518,000	1,500,000

In 1929 there were sixteen medical high schools with 15,000 students, in 1934 the number of medical students was 50,000 and the number of medical high schools was 31. In this number are included five medical high schools working with large hospitals. For building and equipping these medical establishments, 6,400,000 rubles was assigned in 1933 and 38,000,000 rubles in 1935. Up to the present time 40 per cent of the hospitals and 35 per cent of the polyclinics and ambulatoriums have their own rooms for physical therapy, x-ray equipment and clinical laboratories.

The scientific work is done in thirty-three central and 154 outlying investigation institutes of the People's Commissariat for Health. Scientific work is carried on in all medical high schools.

Increased Appropriation for Public Health

The government has decided to assign 370 million rubles to increase the wages of medical workers. Physicians who have scientific degrees will receive increased wages. This increase in wages concerns also midwife and junior medical workers, dentists and chemists. The wages of medical workers in the outlying districts are increased from 10 to 20 per cent, depending on what work they are doing. The increase of wages for workers occupied in the extreme north of the country is 50 per cent. To improve the food for hospital patients the daily ration is increased in towns from 1 ruble 75 copecks to 2 rubles 80 copecks and in the country from 1 ruble 30 copecks to 2 rubles.

This decision, published March 5, is signed by the president of Sovnarkom (Council of People's Commissariat), Vladimir M. Molotov, and the general secretary of the Central Committee of the All Russian Communist Party (Bolshevik), I. V. Stalin.

The Campaign Against Malaria

The laboratories of the Academy of Science of the Union of Socialist Soviet Republics in April 1933 produced the preparation 'acrichin' (which is identical to the German preparation 'atabrine') and gave it to the Tropical Institute of the People's Commissariat for Health where clinical trials made on several thousand patients have shown that acrichin has great therapeutic activity. The dose required for complete recovery from malaria is much less than that of some other preparations. It is much less bitter and does not cause ringing in the ears. The government will build two factories for making acrichin.

To establish an international plan for testing synthetic anti-malaria preparations, a commission of the hygienic committee of the League of Nations was summoned at Moscow, February 20, under the presidency of Professor Sergent (director of the Pasteur Institute at Algiers). The members of the commission were Professor Chooka of Rumania, Dr. Hackett of the Rockefeller Foundation, Dr. Annigstein of Poland, Dr. Lega of Italy, Dr. Pampana, secretary of the malaria committee of the League of Nations, and Soviet scientists. After the meeting the members of the commission went to Gorki (former Nizhni-Novgorod), where they became acquainted with the mass application of acrichin at Sormovo, a suburb of Gorki. The commissioners decided to organize a comparative study of the action of synthetic antimalarial preparations for prophylactic and curative purposes in the Soviet Union, Algiers, Italy and Rumania.

Vitamin C in Conifer Needles

The Leningrad Scientific Institute of Nutrition has discovered that the antiscorbutic vitamin C is not only found in foodstuffs but is present in the leaves of red currants, cabbage and the needles of conifers. Out of 1 Kg. of conifer needles a concentrate has been obtained sufficient to protect a man for a month from scurvy.

The institute has set up apparatus for manufacturing concentrates of vitamin C out of cabbage leaves and conifer needles and at present is using daily 100 Kg. of conifer needles. This is the first factory to produce vitamins in the Soviet Union. It is of great importance because now all the northern parts of the country as well as the expeditions to the far north will be completely protected from scurvy.

Medical Congresses in 1935

This year there will be held thirty-five conferences, meetings and congresses instead of the four that took place last year. In Moscow the All-Russian meeting on Pharmaceutical Education will convene March 2. The ninth All-Union Congress of Obstetricians and Gynecologists will meet March 10-15. The All-Union Conference of Endocrinologists will meet March 25-29. At Kazan the fourth All-Union Congress of Ophthalmologists will meet May 15-19. At Leningrad the fourth All-Union Congress of Nose, Ear and Throat Specialists will meet May 7-11 and the twelfth All-Union Congress of Internists, May 25-30.

Lectures in Lithuania by Soviet Physicians

The endocrinologist Prof. Nicolas A. Cherechevsky and the therapist Prof. David D. Pletnjev gave a series of lectures at Kaunas, the capital of Lithuania, under the auspices of the State University.

A reception was given for the Soviet scientists by the minister of foreign affairs, Mr. Lozoraitis. Professors Cherechevsky and Pletnjev were invited to repeat this course of lectures in Lithuania in the near future.

Marriages

JAMES CHARLES CHAMBERS JR., Kansas City, Mo., to Miss Mary Josephine Crane of Elizabeth, N. J., April 13.

LOUIS B. LAPLACE, Philadelphia, to Miss Delphine L. R. Hollingsworth of West Chester, Pa., May 4.

JAMES EDWIN WISSLER, Washington, D. C., to Miss Lola C. Johnson of Winchester, Va., March 24.

SAMUEL H. SMITH, Cincinnati, to Miss Frances Pauline Brown at Dayton, Ohio, April 24.

JOSEPH DIXON ROBERTS JR., Longview, Texas, to Miss Virginia Lewis of Dallas, March 29.

JAMES W. DAVIS, Dongola, Ill., to Miss Marie Kelly of St. Louis, Nov. 28, 1934.

CODY A. COX, Morton, Ill., to Miss Helen Jane Beitel of Aurora, March 13.

Deaths

George Emmett Bethel † Galveston, Texas, University of Texas School of Medicine, Galveston, 1923, dean and professor of tropical medicine at his alma mater since 1928, instructor of anatomy, 1920-1921, adjunct professor, 1923-1924, and associate professor in 1926, physician to men, university health service, University of Texas, Austin, 1926-1927, and director, 1927-1928, assistant chief resident physician to the Philadelphia General Hospital, 1925-1926, fellow of the American College of Physicians, member of the American Society of Tropical Medicine and the American Heart Association, aged 40, died, April 17, of chronic nephritis.

Edward Blair Sutphen, Morristown, N. J., Columbia University College of Physicians and Surgeons, New York, 1902, member of the Medical Society of New Jersey and the American Laryngological, Rhinological and Otolological Society, fellow of the American College of Surgeons, on the staffs of the Morristown Memorial and All Souls hospitals, Morristown, the Overlook Hospital, Summit, and the New Jersey State Hospital, Greystone Park, aged 58, died, April 18.

Charles Russell Barber † Rochester, N. Y., University of Buffalo School of Medicine, 1882, past president of the Medical Society of the County of Monroe, founder, formerly on the staff and past president of the board of directors of the Park Avenue Hospital, and on the staff of the Monroe County Hospital, for many years member of the board of managers of the Iola-Monroe County Tuberculosis Sanatorium, aged 79, died, April 5, of cerebral hemorrhage.

George Herbert Burnham, Toronto, Ont., Canada, Trinity Medical College, Toronto 1875, F.R.C.S., Edinburgh 1881 and M.R.C.S., England, 1881, University of Toronto Faculty of Medicine, 1889, emeritus professor of ophthalmology and otology, University of Toronto Faculty of Medicine, on the staffs of the Toronto General and St. Michael's hospitals, aged 84, died, April 1, of pneumonia.

Charles Emil Brack † Baltimore, College of Physicians and Surgeons, Baltimore, 1895, formerly professor of clinical obstetrics, University of Maryland School of Medicine, fellow of the American College of Surgeons, treasurer of the Medical and Chirurgial Faculty of Maryland, on the staff and member of the board of governors of the Mercy Hospital, aged 69, died, April 4, of myocarditis.

Albert Milton Beal † Moline, Ill., Drake University Medical Department, Des Moines, 1894, formerly a lawyer, president of the Western College, Toledo, Iowa, 1890-1891, at one time mayor of Toledo, Iowa, for many years president of the board of education of Moline and bank president, on the staff of the Moline Public Hospital, aged 81, died, April 3, of coronary thrombosis.

Charles W. Youngman, Williamsport, Pa., Jefferson Medical College of Philadelphia, 1883, member of the Medical Society of the State of Pennsylvania, past president of the Lycoming County Medical Society, county health officer at one time member of the city board of health and health officer, for many years on the staff of the Williamsport Hospital, aged 76, died, March 5.

William Richard Tinker, Manchester, Conn., University of the City of New York Medical Department, 1880, member of the Connecticut State Medical Society, for many years health officer, in 1897 member of the state legislature, aged 81, on the staff of the Manchester Memorial Hospital, where he died, March 23, of rupture of an aneurysm of the abdominal aorta.

John William Warnick, Johnsonburg, Pa., Western Pennsylvania Medical College, Pittsburgh, 1896, member of the Medical Society of the State of Pennsylvania, at one time county medical director, and for twenty-five years member of the board of health in Johnsonburg, aged 71, died, April 12, of cerebral hemorrhage, arteriosclerosis and diabetes mellitus.

Robert Henry Craig, Montreal, Que., Canada, McGill University Faculty of Medicine, Montreal, 1896, an Associate Fellow of the American Medical Association, member of the American Laryngological, Rhinological and Otolological Society, fellow of the American College of Surgeons, on the staff of the Montreal General Hospital, aged 59, died, March 23.

Thomas Arthur Pettepiece † Freeport, Ill., College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1910, past president of the Stephen County Medical Society, on the staffs of the Evangelical Deaconess Hospital and St. Francis Hospital, aged 60, died, April 15, of aortitis and myocarditis.

John Lambert Coffin, Boston, Boston University School of Medicine, 1876, professor emeritus of diseases of the skin at his alma mater, formerly member of the school committee and board of health of Medford, at one time chairman of the board of trustees of the Westboro State Hospital, aged 83, died, March 15, of coronary stenosis.

Albert Burr Nash, Newark, N. J., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1887, member of the Medical Society of New Jersey, fellow of the American College of Surgeons, on the staff of the Hospital of St. Barnabas and for Women and Children, aged 79, died, March 10.

John Milton Phipps, Indianapolis, Ind., Hospital College of Medicine, Louisville, Ky., 1899, also a lawyer and a minister, veteran of the Spanish-American War, at one time assistant in pathology, Indiana University School of Medicine, on the staff of the Indiana Christian Hospital, aged 69, died, April 11, of carcinoma of the kidney.

George Washington Whitney Whiting † Medford, Mass., University of the City of New York Medical Department, 1887, for many years member of the board of education of Somerville, on the staffs of Martha's Vineyard Hospital, Oak Bluff and the Somerville (Mass.) Hospital, aged 70, died, February 14.

Mary Elizabeth Barrell, York Village, Maine, Woman's Medical College of Pennsylvania, Philadelphia, 1897, formerly member of the board of public welfare of Worcester, Mass., at one time on the staff of the Memorial Hospital, Worcester, aged 72, died, March 14, of paralysis agitans and fracture of the neck of the femur.

John Francis Hayes, Waterbury, Conn., University of the City of New York Medical Department, 1879, member of the Connecticut State Medical Society, member of the board of education, 1900-1901, aged 77, died, February 24, in St. Mary's Hospital following an operation for appendicitis, and chronic myocarditis.

Alfred Henry Brauer † Captain, M.C., U. S. Army, Brackettville Texas State University of Iowa College of Medicine, Iowa City, 1931, entered the M. C., U. S. Army, as a first lieutenant in 1932 and in 1934 was promoted to captain, aged 28, died, March 11, of cerebrospinal meningitis.

William Nelson Offutt † Lexington, Ky., Hospital College of Medicine, Louisville, 1902, member of the American Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons, on the staffs of the Good Samaritan and St. Joseph's hospitals, aged 58, died, April 3.

Robert H. Wynyard Powell, Ottawa, Ont., Canada, McGill University Faculty of Medicine, Montreal, Que., 1876, honorary registrar of the medical council of Canada, past president of the Canadian Medical Association, fellow of the American College of Surgeons, aged 79, died, April 4.

George Howard Mayhugh, Westerville, Ohio, Physio-Medical College of Indiana, Indianapolis, 1885, Ohio Medical University, Columbus, 1895, member of the Ohio State Medical Association, formerly a member of the board of education and city council, aged 77, died, April 8.

Edward H. Hayward † Detroit, Detroit College of Medicine, 1904, formerly lecturer in bacteriology and assistant professor of medicine at his alma mater, at one time member of the city health department, aged 61, died, February 24, in the Grace Hospital, of pneumonia.

Edward Randolph Turnbull, Lawrenceville, Va., University of Virginia Department of Medicine, Charlottesville, 1884, member of the Medical Society of Virginia, for many years member of the county school board and county health officer, aged 78, died, March 20.

John Fogo Doudna, Lake City, Mich., Barnes Medical College, St. Louis, 1899, member of the Michigan State Medical Society, served during the World War, formerly village president, health officer and member of the board of education, aged 60, died, April 9.

Franklin Edward Collins † Brookhaven, Miss., Vanderbilt University School of Medicine, Nashville, Tenn., 1905, past president of the Tri-County Medical Society, on the staff of the Kings Daughters Hospital, aged 52, died, April 3, of coronary sclerosis.

William Edward Magruder † Baltimore, Baltimore Medical College, 1895, at one time associate professor of therapeutics, College of Physicians and Surgeons, aged 61, died, March 29, in Miami, Fla., of acute peritonitis and carcinoma of the sigmoid.

William Samuel Evans * Columbus, Neb., College of Physicians and Surgeons, Baltimore, 1903, fellow of the American College of Surgeons, served during the World War, on the staff of St Mary's Hospital, aged 71, died, March 29 of lobar pneumonia

Charles E McCord, Fortville, Ind., Medical College of Indiana, Indianapolis, 1895, member of the Indiana State Medical Association, past president of the Hancock County Medical Society, aged 65, died, March 19, in Greenfield, of cerebral hemorrhage

Joseph Schwartz, Sioux Falls, S D, State University of Iowa College of Medicine, Iowa City, 1893 member of the South Dakota State Medical Association aged 70 died, April 13, of diabetes mellitus, arteriosclerosis and decompensation of the heart

John Henry Fulgham * East St Louis Ill., Marion-Sims College of Medicine St Louis, 1895, past president of St Clair County Medical Society, formerly county coroner, on the staff of St Mary's Hospital, aged 62, died, March 13, of heart disease

Winfield Scott Schley * New York, Columbia University College of Physicians and Surgeons, New York, 1896 fellow of the American College of Surgeons, on the staff of St Luke's Hospital and the Ossining (N Y) Hospital, aged 61 died, April 1

Andrew Augustus Reed, Jeffersonville, Ind. Kentucky School of Medicine, Louisville, 1896, served during the World War, formerly county jail physician aged 67 died, March 31, in a hospital at Indianapolis, of diabetes mellitus and gangrene

Frank Herbert Coffin * Haverhill, Mass., Boston University School of Medicine, 1900, past president of the Essex North District Medical Society served during the World War aged 61, was found dead in bed, April 7, of coronary sclerosis

Charles Henry French, Pawtucket, R I., Bellevue Hospital Medical College, New York, 1880 member of the Rhode Island Medical Society, formerly bank president, at one time health officer of Waterbury, Conn., aged 76, died, March 4

David McClelland Perkins, Pittsburgh, Western Pennsylvania Medical College, Pittsburgh 1893, member of the Medical Society of the State of Pennsylvania aged 70 died, March 31, of chronic nephritis, hypertension and cerebral thrombosis

Otto Carl Stutz, Upper Sandusky, Ohio Cleveland College of Physicians and Surgeons Medical Department of the University of Wooster, 1885, member of the Ohio State Medical Association, county coroner, aged 70 died, February 28

Warren E Taylor, Moline, Ill., Hahnemann Medical College and Hospital, Chicago, 1877 at one time mayor and health officer of Monmouth formerly managing officer of the East Moline (Ill.) State Hospital, aged 80 died, March 31

Seth Conway, Sharpsburg, Ky., Kentucky University Medical Department, Louisville, 1905 member of the Kentucky State Medical Association aged 55, died, April 3, in the Good Samaritan Hospital, Lexington, of cerebral hemorrhage

John C Preston, Avon, N Y., University of Buffalo School of Medicine, 1892 member of the Medical Society of the State of New York health officer of the village of Avon aged 68, died, March 14, of angina pectoris and arteriosclerosis

Samuel M Sacks, Washington, D C., George Washington University School of Medicine Washington, 1907, member of the Medical Society of the District of Columbia, aged 54, died, February 14, of nephritis and diabetes mellitus

Karl P Hampton, Seminole, Okla., American Medical College, St. Louis, 1904, member of the Oklahoma State Medical Association, aged 58 died, March 3, in St Anthony's Hospital Oklahoma City, of adenocarcinoma

Alexander Heustis Dean * Wilkes-Barre, Pa. Jefferson Medical College of Philadelphia, 1900 on the staff of the Nanticoke (Pa.) State Hospital aged 59 died, March 19, in the Easton (Pa.) Sanitarium, of myocarditis

Alvin Zenas Stoner, Bedford Valley Pa. University of Pittsburgh School of Medicine, 1912 member of the Medical Society of the State of Pennsylvania served during the World War aged 48 died suddenly February 23

William Clinton Sheehy, New Bedford Mass. University of the City of New York Medical Department, 1890 served during the World War aged 69 died suddenly, April 13, of angina pectoris and chronic myocarditis

Hugh Joseph McDonald, Butte Mont. McGill University, Faculty of Medicine, Montreal Que., Canada, 1885 member of the Medical Association of Montana on the staff of the Murray Hospital, aged 73 died March 22

Alexander Wilson Pollock, Addis Ababa, Abyssinia, Africa, Western Pennsylvania Medical College, Pittsburgh, 1901, for many years a medical missionary, aged 59, died in February, of cerebral hemorrhage

Alfred McNally, Lethbridge, Alta, Canada, University of Toronto Faculty of Medicine, 1905 fellow of the American College of Surgeons on the staffs of the Galt and St Michael's hospitals aged 52, died, April 1

Nicholas Walter Kelly, Memphis, Tenn., Memphis Hospital Medical College, 1900, member of the Tennessee State Medical Association served during the World War, aged 57, died March 23, of pneumonia

Charles Porter McKee * St Marys Ohio, Starling Medical College Columbus, 1905 past president of the Auglaize County Medical Society, member of the school board, aged 54, died, March 29, of pneumonia

William Henry Beardsley, Springfield, Vt., Yale University School of Medicine, New Haven, Conn. 1910, formerly member of the state legislature, aged 52, died, March 2, in a hospital at Hanover, N H

Lena Honegger Bertschinger, Rancho Santa Fe, Calif., Universität Zürich Medizinischen Fakultät, Zurich, Switzerland, 1891, aged 67, died recently, of cerebral hemorrhage, arteriosclerosis and hypertension

Harry Leo Tapperman, Benson, Ariz., University of Michigan Medical School, Ann Arbor 1930 member of the Arizona State Medical Association, aged 28, died, February 23, in Los Angeles

Alfred Byrd Phillips, Dora Ala., Vanderbilt University School of Medicine, Nashville Tenn., 1883 aged 74, died, March 5, in a hospital at Birmingham, of lobar pneumonia and diabetes mellitus

Joseph A McGee, Big Springs, Ind., Physio-Medical College of Indiana, Indianapolis, 1883 aged 84, died, April 16, in the Witham Memorial Hospital, Lebanon, of endocarditis and arteriosclerosis

Charles Winn Williams * Cedartown, Ga. Birmingham (Ala.) Medical College, 1913, formerly secretary of the Polk County Medical Society, aged 45, died, March 8, of influenza and pneumonia

Adelbert Britton Deynard, New York, Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1875, aged 85, died, March 21, in Owen Sound, Ont., of cardiovascular degeneration

Bernard Francis McGaffigan, Boston Tufts College Medical School, Boston, 1904, on the staff of the Deer Island Hospital aged 56, died, April 2, in the Boston City Hospital, of heart disease

Harold Pederson, Minneapolis University of Minnesota College of Medicine and Surgery, Minneapolis 1907, member of the Minnesota State Medical Association aged 61, died in March

John Edmund Dehoff, York Pa., Southern Homeopathic Medical College, Baltimore, 1897, member of the Medical Society of the State of Pennsylvania, aged 62 died, February 16

Edgar Eynon Chivers, Mannsville Okla., Rush Medical College, Chicago, 1899, member of the Oklahoma State Medical Association aged 59, died, March 23, in Ardmore, of pneumonia

James Ritchie Robertson, Halifax, N S, Canada, McGill University Faculty of Medicine, Montreal, Que., 1925, aged 34, died, February 27, in the Glace Bay (N S) General Hospital

Marion B Richards, Harleton, Texas, Hospital College of Medicine Louisville, Ky. 1905 member of the State Medical Association of Texas, aged 59, died, February 4, of pneumonia

Thomas M Calvert, Mannington, W Va. Baltimore University School of Medicine, 1892, member of the West Virginia State Medical Association, aged 94 died, March 2

Byron J Lillibridge, Brantree, Mass. Jefferson Medical College of Philadelphia 1883 member of the Rhode Island Medical Society, aged 74, died, March 20, in Miami, Fla

Charles B Chenoweth, Nora Springs Iowa Rush Medical College, Chicago, 1884, aged 77, died, March 28 in a hospital at Mason City, of coronary occlusion and acute mastoiditis

Mark Tenney Phy Baker, Ore., Rush Medical College, 1926 aged 36 died March 29, in St Vincent's Hospital, Portland Ore., of peripheral neuritis and bronchopneumonia

Lewis McClure Campbell, Red Sulphur Springs, W Va. College of Physicians and Surgeons, Baltimore, 1887, aged 71, died, March 31, of carcinoma of fundus of the stomach

Joseph Shelor Stribling, Seneca, S C. Bellevue Hospital Medical College, New York, 1888, an Affiliate Fellow of the American Medical Association, aged 71, died, March 16

Samuel Jones Hayes, Pine Plains, N. Y. Medical College of the State of South Carolina, Charleston, 1932, aged 37, died, March 7, in a hospital at Baltimore, of multiple sclerosis

Rudolph Adam Constien & Ashland, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1900 served during the World War, aged 57, died, March 24

John William Hooper, Roanoke, Ala. Jefferson Medical College of Philadelphia, 1884 served during the World War, formerly county health officer, aged 70 died, March 18

Edward St. Clair Furay, Omaha, John A. Creighton Medical College Omaha, 1895, served during the World War, aged 65 died, March 6 of arteriosclerosis and myocarditis

Gustave August Andre & Hartford Conn. University of the City of New York Medical Department, 1895, aged 64, died March 19, in the Hartford Hospital, of heart disease

Albert Clement Shute, Pottstown Pa. Hahnemann Medical College and Hospital of Philadelphia 1891 on the staff of the Homeopathic Hospital, aged 67, died in March

William Munroe Urkart, West Bend Wis. Milwaukee Medical College Milwaukee 1907 aged 56 died suddenly, April 7, in the Wisconsin General Hospital Madison

William Righter McNair, Los Angeles Jefferson Medical College of Philadelphia, 1899 also a pharmacist, served during the World War, aged 61 died suddenly, March 26

William Lyle Allred, San Francisco Stanford University School of Medicine San Francisco 1931 radiologist to the San Francisco Hospital aged 50 died March 7

William Bertram Scott & Seattle George Washington University School of Medicine Washington D. C. 1908 aged 60 died, March 12, of carcinoma of the rectum

Abraham Lincoln Preston, Brookville Ind. Medical College of Indiana Indianapolis 1884 aged 74 died February 23, of chronic myocarditis and cerebral hemorrhage

Thomas McClelland Faddis, Charleston Pa., Jefferson Medical College of Philadelphia 1894 for many years member of the school board, aged 70, died March 21

William E. McGlasson, Commerce Texas (registered by Texas State Board of Medical Examiners, Act of 1907) aged 61 died, March 17, of cerebral hemorrhage

James Henry Slaughter & Kilgore Texas Mississippi Medical College, Meridian 1912 member of the Arkansas Medical Society, aged 48, died March 17

J. Wesley Price, Booneville Miss. University of Virginia Department of Medicine, Charlottesville, 1894, aged 63 died March 25, of septic thrombosis and pyemia

Harry A. Roach, Chicago College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1905, aged 53, died March 20

William R. Froneberger, Maryville Tenn. Tennessee Medical College Knoxville, 1896 aged 60 died March 14, in the Knoxville (Tenn.) General Hospital

Hiram Allen Buell, Prairie Farm Wis. Wisconsin College of Physicians and Surgeons, Milwaukee, 1910, served during the World War, aged 50, died, March 20

Howe A. Jordan, Big Island, Va., College of Physicians and Surgeons, Baltimore 1879, member of the Medical Society of Virginia, aged 82, died March 13

Charles Herman Hofmann, Los Angeles New York Homeopathic Medical College 1879 aged 79, died, February 26, in the Cedars of Lebanon Hospital

Percy Campbell Overstreet, De Kalb, Miss., University of Nashville (Tenn.) Medical Department, 1908, aged 52 was found dead, April 13, of heart disease

John Everette Siler, Lot, Ky., Hospital College of Medicine Louisville, 1903, served during the World War, aged 57, died, March 3, of multiple sclerosis

William Porter Wilkin, New York, Bellevue Hospital Medical College New York, 1885 aged 73 died recently in Wilmette, Ill., of lobar pneumonia

Louis J. Toussaint, Milwaukee, Milwaukee Medical College, 1896, aged 67, died, March 24, in the Mount Sinai Hospital, of coronary thrombosis

Jesse M. Abston, Monroe Township, Ind., Central College of Physicians and Surgeons, Indianapolis, 1880, aged 86, died recently, of cerebral hemorrhage

John Wesley Le Seur, Batavia N. Y. Hahnemann Medical College and Hospital of Philadelphia, 1886, aged 77, died, March 10 while aboard a tram

Samuel McKibbin & Creede, Colo., Victoria University Medical Department, Coburg, Ont., Canada, 1888, aged 76, died, March 29, of myocarditis

Robert Thomas Hill, St. Louis, Jefferson Medical College of Philadelphia, 1865, Civil War veteran, aged 97, died, March 23, of chronic nephritis

Walter Tremaine Purdy, Amherst, N. S., Canada McGill University Faculty of Medicine, Montreal, Que., 1913, aged 48 died, March 21, at Montreal

Leo S. Talaska, Toledo, Ohio, Toledo Medical College, 1898, aged 59, died, March 11, in St. Vincent's Hospital, of pneumonia and heart disease

Beverley Louis Rosswell Kelly, Fordwich, Ont. Canada, University of Western Ontario Medical School, London, 1930, aged 29 died, February 22

Theodore Jefferson Catlin, Buffalo, Minn., Rush Medical College Chicago, 1874, aged 86, died, March 16 in the Catlin Hospital, of pneumonia

George Washington Hogle, Mount Vernon, Iowa, Miam Medical College Cincinnati, 1891, aged 74, died, February 10 in Pasadena, Calif.

Charles Granville Duncan & Socorro, N. M., University of Maryland School of Medicine, Baltimore, 1881, aged 85, died, March 27

Charles Fremont Sherman, Stone Ridge, N. Y., University of Vermont College of Medicine, Burlington, 1890, aged 78, died, March 3

Alfred J. Skiles, Kenton, Tenn. Memphis (Tenn.) Hospital Medical College, 1893, aged 71, died, March 25, in a hospital at Memphis

Thomas O. Douglass, Eupora Miss. (licensed in Mississippi in 1890) also a druggist aged 67, was found dead in April of heart disease

Josephine Antonia Jewett, Berkeley Calif., Oakland (Calif.) College of Medicine and Surgery, 1917, aged 65, died February 17

William John Jackson, San Francisco, College of Physicians and Surgeons of San Francisco, 1898, aged 68, died, February 1

Walter Theron Travis, Dalhart, Texas, Hospital College of Medicine, Louisville Ky. 1907, aged 48, died recently, of septicemia

Stacy Burchard Hall, Healdsburg Calif., Medical Department of Omaha (Neb.) University, 1901, aged 55, died, February 17

Alta M. Kesler Boram, South Bend Ind., Eclectic Medical Institute, Cincinnati, 1905, aged 53, died, April 12, of diabetes mellitus

Laurence Reginald Ryan, Santa Barbara Calif., Jefferson Medical College of Philadelphia, 1888, aged 76, died, February 4

Hiram Whisler, Tingley, Iowa (licensed in Iowa in 1887), aged 85 died, February 20, in Des Moines, of chronic myocarditis

Charles Henry McElfresh, San Diego, Calif., Marion Sims College of Medicine, St. Louis, 1898, aged 71, died, in March

Augustus Milleg, New York University of the City of New York Medical Department, 1889, aged 67 died, March 13

Edwin Lyttelton Paulding, Arroyo Grande, Calif., Medical College of Ohio, Cincinnati, 1882, aged 85 died, February 23

George Lew Chee, Los Angeles, University Medical College of Kansas City Mo., 1911, aged 48, died, February 26

George Monroe Peavler, Bristol, Tenn. Hospital College of Medicine, Louisville, Ky. 1889, aged 76 died, March 24

Emerson Boynton, Lancaster, Pa. College of Physicians and Surgeons, Baltimore, 1897, aged 62, died February 24

Joseph Marsh Martin, Lewes, Del. Jefferson Medical College of Philadelphia, 1894, aged 62, died, March 30

Callie F. Johnson, Hatfield, Ark. (licensed in Arkansas in 1903), aged 72, died, March 17, of mitral insufficiency

Harry P. G. Edsell, Liberty, Ind. (licensed in Ohio in 1897), aged 94 died recently, of bronchopneumonia

Henry N. Princehouse, Smackover, Ark. (licensed in Arkansas in 1903), aged 66, died recently

James N. Reeves, Baytown, Texas (licensed in Texas under the Act of 1907), aged 73, died in March

Albert Ellsworth Froom, Belvidere Ill., Chicago Medical College, 1886, aged 73 died, March 4

Bureau of Investigation

A E G HALL

Bringing the Criminal Record of This Quack in the Psychology Field Down to Date

Hall is again loose after two years incarceration in the Kingston, Ontario Penitentiary. Readers of this department of THE JOURNAL may remember an article published Oct. 13 1928, on one A E G Hall who worked the quack psychology racket. According to information collected, Hall's name is Alfred Ernest Edward George Hall and not content with having most of the letters of the alphabet conferred on him at birth before his name he has adopted for use after his name the titles M.D., Ps.D. M.Sc.D. B.A. F.P.S.A., B.L." and possibly some others. Needless to say the man is not a physician, has never attended any reputable medical school or been licensed to practice anywhere in the United States or Canada.

Hall is said to have been born in London in 1892 and to have been brought to Canada by his parents a year later. He apparently acquired Canadian citizenship, and since he has been grown, has made at least three trips to England.

A few years ago Hall claimed under oath that he held a degree in medicine granted by the McKeechrie School of Medicine of Victoria, B.C., in 1916. There is no such institution and never has been. Hall also claimed to have attended "Ballie College" of the University of London for three years and to have obtained the degree of B.A. at that institution. There is no Ballie College and Hall has never been graduated by the University of London. Hall also claimed during one of the numerous times that he has been under arrest that from 1916 to 1918 he was the Executive Director of the Belgian War Orphans Relief for the Dominion of Canada. This was another story made up out of whole cloth.

During the various times that Hall came to the United States, he called himself a consulting psychologist. When he was in Chicago he posed as a specialist of London, Paris, Geneva and Vienna—and possibly points east—and discoursed on "Sex and Civilization." In fact, sex has been Mr. Hall's

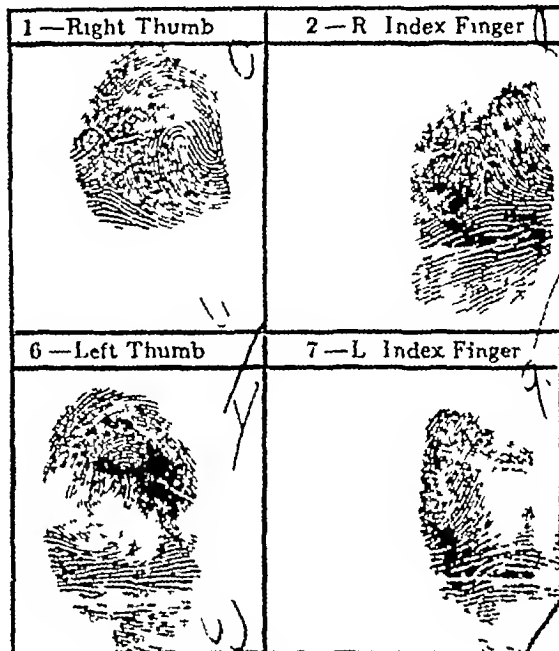

Photographs of A E G Hall. Left taken at the time he entered Kingston (Ont.) Penitentiary, August 1933. Right taken when he was liberated from the penitentiary, in February 1935.

forte. At one time when Hall was in Toronto the weekly publication *Saturday Night* of that city described Hall as a 'sexual quack' who was giving utterly filthy and unscientific discourses on sexual subjects. He gave the same sort of stuff in the United States, and the Bureau of Investigation received from some persons who were present at his talks statements declaring that Hall showed a sadistic tendency. For some time Hall operated at Richmond Ind. where he is said to have created a fake organization called the "American

Academy of Psychological Research" and to have appointed himself 'Dean' of the "Academy." The thing, of course, had not the slightest educational standing, it had connected with it a motley group of faddists, fakers or quacks. It distributed degrees lavishly. Curiously enough, most of the attendants at this so-called Academy hailed from eastern Canada.

In April, 1926 Hall came to Chicago allegedly to attend a conference in the anti-narcotic cause" and to create a local

Some of the fingerprint records of Alfred E. Hall from the files (No. 46612) of the Federal Bureau of Investigation of the U. S. Department of Justice.

organization and deliver a series of lectures. Hall claimed that he had been engaged by the "International Order of Crusaders" at a salary of \$12,000 a year and expenses. He was also to receive 50 per cent of the registration fees of those who would take his 'course,' as well as such fees as he could wrangle out of the public in his pose as a "consultant psychologist." While in Chicago, Hall was arrested for obtaining money under false pretenses and working a confidence game. He was fined and sent to the House of Correction for six months. He was also arrested in Illinois for violation of the medical practice act of that state, but, as so often happens, the case had to be *nolle prossed* due to the mysterious disappearance of a witness. When Hall was arrested in Chicago in July, 1927, he claimed that he had been the "financial chairman" for Aimee Semple McPherson when she had her 'revival meetings.'

Hall's police record, so far as the Bureau of Investigation has it—and it is possibly incomplete—is as follows:

1923—Vancouver. arrested for obtaining credit under false pretenses. Sentence suspended.

1924—Vancouver. arrested for conspiring to defraud. Case dismissed. Again arrested charged with obtaining money under false pretenses and sentenced to six months at hard labor in Oakalla Prison.

1925—Vancouver. arrested for obtaining money under false pretenses. Sentenced to twelve days. Again arrested for obtaining money under false pretenses and sent to jail.

1926—Chicago. arrested on charge of operating a confidence game and obtaining money under false pretenses. Was fined and sentenced to six months in the House of Correction.

1927—Chicago. arrested for practicing medicine without a license. Charge *nolle prossed* for lack of prosecution. At the same time Hall was taken into custody by the United States authorities as an alien who had violated the Immigration Act. He was given hearing and deported.

1928—Toronto. arrested on the charge of vagrancy. Charge withdrawn, as he had money in his pocket.

1930—Toronto. arrested for swindling the Royal York Hotel of about \$1,100. Sentenced to six months in the Ontario Reformatory.

1932—Cleveland. arrested by the police department and again deported to Canada.

1933—Toronto. arrested and found guilty of theft. Sentenced to two years in the Kingston Penitentiary.

Hall's escapade in Toronto in 1930 consisted, first, in running up a bill of \$220 at the King Edward Hotel, according to the Toronto papers of February, that year. In April, 1930, Hall again made the front page, this time by giving a banquet at the Royal York Hotel of Toronto, at which Sir Geo. C. Foster is alleged to have spoken. The banquet cost \$1,000 and the total amount of credit that Hall obtained from the Royal York Hotel was more than \$1,100. He was charged with obtaining credit by false pretenses, pleaded not guilty and elected trial by jury. According to the assistant manager of the hotel, Hall, who had introduced himself as "Doctor," had stated that he was general organizer of the National Order of Canada, which, he alleged was in a flourishing condition, highly organized, and was paying him \$12,000 and expenses. Investigation proved that the National Order of Canada was not in a flourishing condition, it actually had not more than seventy-five members, and, of course Hall was not in receipt of any salary. On May 9, 1930, Hall was convicted and sentenced to six months determinate and six months indeterminate in the Ontario Reformatory. When asked if he had anything to say, Hall struck a dramatic pose and declared that he had been systematically hounded by the authorities.

Not content with this sample of Ontario justice Hall in 1933 was put on trial in Toronto on a charge of theft. Hall and one Fred Hastings with whom he was associated were alleged to have stolen \$2,482 paid to them as subscriptions for various magazines and periodicals while they operated an organization known as the Dominion Publications Bureau. Hall acted as his own attorney and in addressing the jury he said: "You have not before you the ordinary type of criminal that goes out to plunder and steal." He pleaded "justification and honest error." Hall told the jury, also, that he had written books about criminals, had looked after them spiritually, had studied them psychologically and their actions were not the same as his own. He again charged that he was being hounded by the authorities. Hall was very persuasive and dragged the usual red-herrings across the trail and the judge, in charging the jury, warned them not to allow themselves to be carried away "by frenzied eloquence." They did not. Hall was sentenced to two years in the Kingston Penitentiary.

A few weeks ago Hall completed his two year sentence in the penitentiary. Apparently no sooner was he out of the penitentiary than he hired a hall, in accordance with his usual methods, and as the Toronto *Evening Telegram* reported, "smartly dressed in striped trousers, black coat, wing collar and flowing tie," addressed an audience—of less than a hundred—telling them what an unpleasant place the Kingston Penitentiary is. He also made charges against the warden of the penitentiary and the Hon. D. M. Ormond Superintendent of Penitentiaries at Ottawa. Hall is reported to have stated to his audience that he didn't regret his experience in the penitentiary and that since getting out he had written a 100 page report. He claims to have been one of those sentenced to be paddled while he was in the penitentiary, but it appears from the report that, unfortunately for the public—and possibly for Hall himself—the sentence was not carried out.

The reason for calling attention to A. E. G. Hall is that this quack and ex-convict is more than likely to make another attempt to get into the United States. If he does, it can be taken for granted from his past record that he will live by his wits and at the expense of the American public.

American Classics in Medicine—I would plead for a larger interest in the historical method of approach to our subjects. There is a fascination in books not only merely for their contents, but for something about the author it may be, or something about the period, something occasionally about the binding. In other words, there is an opportunity for the bibliophile, some like to call him a bibliomaniac. There is an opportunity for him in medicine as well as in general literature. There are books and collections of works that mark eras and they are called Medical Classics. This is a very attractive thing, rather expensive I will admit, but you can now and then pick up such things. We have our classics, even American Classics in medicine—Welch, W. H. History of Pathology, *Bull. Hist. Med.* 3:1 (Jan) 1935.

Correspondence

DIAGNOSIS BY CULTURAL METHODS OF RECTAL GONORRHEA IN WOMEN

To the Editor—In THE JOURNAL, January 19, p. 192, Martin called attention to the not uncommon complication arising from rectal gonorrhea in women with genital gonorrhea. He however bases his diagnosis of rectal gonorrhea on microscopic examination of smears made from material swabbed from the rectal wall. He rejects the cultural method, as he thinks that the results are inconclusive. But it should be admitted that a diagnosis made from the examination of smears from the rectum is often unreliable, especially in view of the occurrence of gram negative cocci and coccobacilli of the fecal flora in such smear preparations.

Contrary to the views held by Martin on the value of cultural methods for the diagnosis of rectal gonorrhea, I find that cultural methods give excellent results and that diagnosis by culture is much more reliable than by microscopic examination of smears (Ruys, A. Charlotte, and Jens, P. A. *München med. Wchenschr.* 80:846 [June 2] 1933).

Out of eighty-two women with genital gonorrhea that I investigated, forty-eight (60 per cent) were positive for gonococci in cultures at the first examination. Gonococci were also invariably isolated by culture from the rectum of children with gonorrhoeal vulvovaginitis. All the thirty-eight children that were examined were positive for gonococci by the cultural method.

The following comparative statement of results by the cultural method and by the microscopic method brings out the greater reliability of the cultural method in diagnosis of gonococcal infection of the rectum.

Smear positive culture positive	48
Smear positive culture negative	3
Smear doubtful culture positive	23
Smear doubtful culture negative	3
Smear negative culture positive	46
Smear negative culture negative	218

In seventy-two cases in which smear examination gave a negative result or a doubtful finding, sixty-nine cases were positive for gonococci in culture.

The mediums that I use are Bieling's blood-water agar and Levinthal's agar with ascitic fluid, both of which gave good results. I use a slightly modified procedure for the preparation of the Bieling medium (Ruys, A. Charlotte. *Centr. Bakt.* orig. 127:280 [Jan 30] 1933). Blood drawn from a horse is immediately diluted with an equal part of distilled water and kept in a bath at 60 C for thirty minutes. After that period, two parts of this are mixed with three parts of nutrient agar. It is desirable to dry the medium slightly before inoculating. The mediums are warmed slightly before inoculating. The material is obtained by scraping softly the mucosa of the rectum with a strong platinum loop and transferring a very small bit of mucus or the scraping on to the culture medium. It is then very carefully spread on the surface of the medium by means of a Drigalski spatula on two blood agar plates and two Levinthal's ascites agar plates. The plates are incubated at 37 C. in containers with water at the bottom to prevent excessive evaporation. In twenty-four hours the gonococci grow into discrete colonies and in forty-eight hours they are much larger and are characteristic in appearance. They can then be easily distinguished from the colonies of fecal organisms. The gonococcus colonies are translucent, irregular, raised above the surface of the medium, moist and grayish. Subcultures were always made for further determination.

The patients from whom these examinations were made consisted of children and women. The women were patients with genital gonorrhea either in an acute stage or in a chronic stage.

Eight out of forty-eight women that were positive for gonococcal infection of the rectum complained of slight pain and only one suffered from severe symptoms. The others had no symptoms.

Gonococcal infection of the rectum is often overlooked and, as mentioned by Martin, the infection could be recognized only if specially looked for. In the diagnosis of the infection, the examination of smears from the rectum is not as reliable as the cultural method of diagnosis. By means of cultures a larger number of cases were found to be positive, while by the examination of smears many of the positive cases escaped detection.

A CHARLOTTE RUIS, M.D., Amsterdam, Holland
Director, Municipal Health Laboratories

TREATMENT OF PELLAGRA

To the Editor—In *THE JOURNAL*, April 20, 1935, page 1377, was an article by Dr. Tom D. Spies on the treatment of pellagra. It is surprising that Dr. Spies made no mention of the achlorhydria or hypochlorhydria that all pellagrins show. In a series of fifty patients from Tennessee and the Carolinas that I have studied it was found that the use of dilute hydrochloric acid in the treatment of pellagra immediately improved the stomatitis and diarrhea that these patients generally show. It has been my opinion that the achlorhydria has a definite pathologic significance and that one must take cognizance of this fact. Dermatitis, diarrhea, stomatitis and nervous symptoms are late manifestations of the disease but an achlorhydric anemia is an early manifestation.

MARVIN SANDORF, M.D., Indianapolis

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

TREATMENT OF LOCOMOTOR ATAXIA

To the Editor—A white man aged 36 married with no children, had no complaints referable to any system except frequent headaches on the top of the head and difficulty in falling asleep. The past history was essentially negative except that about sixteen years before he had a blister on the penis which healed spontaneously after a few weeks. A routine examination revealed Argyll Robertson pupils, an absent left knee jerk, absent ankle jerks and a suggestive positive Romberg sign. The Wassermann reaction was 4+ with both antigens. From April 10 to July 2, 1934 he was given ten intravenous injections of from 0.45 to 0.6 Gm. of neoarsphenamine and twelve intramuscular injections of 2 cc. each of iodohismitol once a week. One month later a lumbar puncture was done. Clear fluid under no increased pressure was obtained. There was no increase in cells and acid chemical tests were negative except for increased globulin. Wassermann and colloidal gold tests were negative. The Wassermann reaction of the blood at this time was still 4+. There were still no subjective complaints except difficulty in falling asleep. There is apparently no mental deterioration. After a rest period of two months the previous plan of treatment was resumed. After nine injections of iodohismitol the Wassermann reaction is still 4+. The diagnosis is apparently *tabes dorsalis*. Will you please outline a scheme for further treatment. Should tryparsamide be used? He weighs 155 pounds (70 Kg.) and there are no apparent visceral lesions. Please omit name.

M.D. New York

ANSWER—In this case the report of a negative Wassermann reaction in the spinal fluid cannot be accepted with certainty unless it is known that the test was carried out with large as well as with small amounts of fluid. A satisfactory Wassermann test on the spinal fluid demands quantitative titration. If the unit of reagents employed by the laboratory in the test is 0.2 to 0.25 cc. the actual test with spinal fluid should be done with amounts of fluid ranging from 0.1 to 1 cc. In patients with *tabes dorsalis* it is not uncommon to find a positive Wassermann reaction in the fluid with large amounts when the test with small amounts is negative. If such a quantitative Wassermann test has not been done, it would be wise to repeat the lumbar puncture at an early date.

If the spinal fluid is actually as stated—normal, except for some increase in protein—it may be assumed with a fair degree

of certainty (and especially in view of the fact that the patient is symptom free and recognizable as *tabetic* only on the basis of physical signs) that he represents an instance of so called *burnt out tabes*, i.e., an inactive process in the nervous system, the neurologic abnormalities representing scars of previous activity. Under these circumstances his treatment may be continued for a minimum of two years with alternating courses of an arsphenamine and a bismuth compound.

These drugs are preferably given in alternation rather than simultaneously, and it is desirable that treatment be continuous rather than intermittent. Rest periods, if interpolated at all, should be short. No attention whatever need be paid to the response of the blood Wassermann reaction.

If, on the other hand, the spinal fluid Wassermann reaction is positive even with large amounts of fluid, it is fair to assume that there is still activity of the infection in the nervous system. It should be remembered that a provocative response may be obtained in the spinal fluid as in the blood and that, even though the fluid may originally have been negative, it may now be definitely abnormal. Under these circumstances it is probably advisable to treat the patient immediately with artificial fever, preferably with malaria. Follow up treatment, after malaria is completed, should consist of alternating courses of an arsphenamine and a bismuth compound for a minimum period of two years.

On the basis of the information supplied, it is probably neither necessary nor advisable to use tryparsamide in this situation. If the *tabes* is inactive, tryparsamide is unnecessary, if it is active, better results, so far as insurance for the future and shortening of the total duration of treatment are concerned, will be accomplished by the use of fever rather than tryparsamide. Finally, visual reactions due to the use of tryparsamide are more common in *tabes* than in other types of neurosyphilis.

The serologic control of treatment should rest entirely on the spinal fluid and not on the blood. The spinal fluid examination should be repeated as a routine procedure at intervals of every six months during and for the first two or three years after the completion of treatment and thereafter yearly or biyearly for the duration of the patient's life.

It goes without saying that the patient's wife should be examined and that, in view of the facts that he has neurosyphilis and that conjugal neurosyphilis is frequent, the examination should include, in addition to a blood Wassermann test, a complete physical and neurologic examination, and laboratory study of the spinal fluid.

PALLOR OF NASAL MUCOUS MEMBRANE AND USE OF HYDROCHLORIC ACID

To the Editor—I have heard it stated frequently that pallor of the nasal mucous membrane is an indication for prescribing dilute hydrochloric acid with meals, particularly in treating patients with chronic atrophic arthritis. This is done apparently regardless of the gastric acidity as revealed in the usual form of gastric analysis. It is supposed to have some beneficial effect on the acidity of the body as expressed in the excreta such as the urine and the body sweat. Will you please discuss the truth or fallacy of these statements and give any references available? Also please explain the probable effects of the continued use of hydrochloric acid by such patients who have an apparently normal gastric acidity to begin with. Kindly omit name and address.

M.D., Massachusetts

ANSWER—There is a school of thought in this country which believes that human beings can be divided into groups depending on whether the sympathetic or the parasympathetic system or a mixture of the two is dominant in the constitution. These three types tend to suffer from certain illnesses and the proper use of certain foods and medications has a pronounced effect on the individual and his complaints. Furthermore, the color of the mucous membrane, in particular that of the nasal septum, is not only an aid in assigning any patient to the particular group to which he belongs but is an index to the success of the therapeutic measures instituted.

Patients who have red nasal mucous membranes are those in whom the sympathetic system is dominant. The diseases frequent in them are infections, hyperthyroidism, atrophic arthritis, diabetes mellitus, cancer and hypertension of the vascular system.

Patients in whom the parasympathetic system is dominant and whose nasal mucous membrane is more or less pale tend to suffer from asthma, hay fever, urticaria, eczema, other allergic diseases, hypothyroidism and hypotension of the vascular system.

For each of these groups there are certain foods to be avoided and others to be taken. The chloride, iodine and chlorophyll intake is important. Patients with red septums should avoid acid ash producing foods, patients with pale septums should be given acid ash producing foods and also therapeutic doses of dilute hydrochloric acid. Full details as to

diagnosis and treatment are given in an article published by D. C. Jarvis in the *Archives of Otolaryngology* (21:131 [Feb] 1935).

There are others who do not accept this thesis and who have attempted to prove their points by clinical experimentation. For instance, in one publication it was determined that 1. No correlation could be found between the color of the nasal mucosa and the clinical symptoms of acidosis in fifty critically ill patients, all of whom showed clinical symptoms of acidosis with hyperpnea, dehydration and acetoneuria. 2. Age influences the color of the nasal mucosa of normal individuals. After 60 the membranes tend to become atrophied and are very pale, while the membranes of infants are very red. 3. Blonds with pale fair skin have pale mucous membranes while brunettes with high color have membranes that tend to be red. 4. Posture, exercise, the use of alcohol, the inhalation of dry air or irritants such as dust influence the color of the nasal mucosa. 5. From these observations it may be concluded that the color of the nasal mucosa varies not only in persons who are ill but also in healthy individuals and that the reasons for these variations are not necessarily of a pathologic nature (Bernheimer L. D. and Cohen D. J. *The Color of the Nasal Septum*, *THE JOURNAL* April 29 1933 p. 1324).

It would perhaps be best to keep an open mind on the ideas expressed by the first mentioned school. Their theories in the minds of many remain unproved yet the treatment recommended is lacking in danger. Their recommendations could be carried out empirically and the results judged on their own merits. More than one method of treatment in medicine has been used successfully for years before the laboratory proof of its worth became available. Digitalis is a remedy of which this is preeminently true.

As to dilute hydrochloric acid it can in all likelihood be taken in therapeutic doses by patients with an apparently normal gastric juice over long periods with safety, provided other factors, such as diet remain normal.

TREATMENT OF SYPHILIS

To the Editor—A man aged 40 first came to me in June 1933 at which time he was found to have a four plus Wassermann reaction. There was a history of a scrotal lesion two months previously. The patient was treated continuously with nearsphenamine and compounds of bismuth and mercury. A course of nearsphenamine usually 0.6 Gm. in series of ten weekly injections, was alternated with courses of a bismuth compound usually bismuth salicylate or potassium bismuth tartrate once or twice a week for from six to eight weeks. To date he has received thirty-two injections of nearsphenamine totaling 18 Gm. thirty-two injections of compounds of bismuth and eighteen injections of mercuric succinimide. The blood Wassermann and Kahn tests were found to be negative following the first course of nearsphenamine and have remained so on repeated testing. In December 1933 the patient was operated on for a deflected nasal septum. He was subject to repeated attacks of nasal catarrh. In April 1934 a plastic iritis of the right eye developed. The ophthalmologist did not feel that it was syphilitic in nature. Local treatment by the ophthalmologist and treatment with nearsphenamine and bismuth compounds were continued at this period in conjunction with potassium iodide by mouth. The eye responded well and in about one month the condition had cleared. Aug. 1, 1934, there developed a keratoiritis of the left eye. The blood Wassermann and Kahn tests taken at this time were negative. Spinal fluid examination showed a negative Wassermann test, the faintest trace of globulin and a cell count of 2. Physical examination was otherwise negative. Two injections of nearsphenamine were given during this attack along with mercuric succinimide. The ophthalmologist was not quite certain whether or not some aggravation of the eye condition occurred following this last injection. Mercuric succinimide three times weekly and potassium iodide were continued. At this time I am in a quandary as to further treatment with nearsphenamine. Is the eye manifestation syphilitic? Is it a manifestation of sensitivity to one of the drugs used in the treatment? This last attack of iritis has now cleared remarkably well. Please omit name and address.

M. D. Ohio

ANSWER.—The treatment has conformed to an adequate general standard for early syphilis. It should be understood, however, that no standard treatment can provide for every phase of special resistance or relapsing tendency in every individual patient. It is therefore conceivable, though unlikely, that the plastic iritis of the right eye is an ophthalmic relapse, even in the presence of a negative blood serologic test. Nearsphenamine at least and possibly also bismuth compounds, have a certain amount of nonspecific effect on eye inflammations and it may be that the therapeutic response described was due to nonspecific rather than to specific effect. Mercuric succinimide also has a certain amount of nonspecific effect, but the suggestion that a flare up followed its use is a little more in keeping with the tuberculous or focal infective than with a syphilitic process. The continuously negative blood serologic

tests and negative spinal fluid at this time still further reinforce the belief that the patient's syphilitic infection is cured or inactive and that the eye condition comes from some other source.

The question as to whether the eye condition can arise from specific sensitivity to any of the drugs used cannot be answered categorically for the range of sensitivity manifestations to the arsphenamines and to bismuth compounds is constantly increasing. It seems, however, improbable that a solitary occurrence of this sort would be the entire story in a specific sensitivity. It would seem more worth while to make a thoroughgoing investigation of tuberculous, focal infective and allergic factors before concluding that the patient is reacting specifically to treatment for syphilis.

Under these circumstances, therefore, a continuance of treatment for syphilis by a method that does not appear to have caused eye flare ups would be in order. For this, bismuth salicylate in courses of eight or ten injections with rest intervals of two months between the courses, for at least another year would appear to be satisfactory. It might be worth while to invoke also a nonspecific protein therapeutic effect by intramuscular injections of whole boiled milk, beginning with 2 cc. once a week and increasing to 10 cc. once a week for a series of ten or even fifteen intramuscular injections. A determined effort should, however, be made to get to the bottom of the eye condition as such without endeavoring to pin every complication such as this on the probably "cured or inactive" syphilis.

HAZARDS OF CARBON TETRACHLORIDE IN TEXTILE MILL

To the Editor—I would greatly appreciate any help you might give me in obtaining information on the prevention of carbon tetrachloride poisoning in a textile mill.

M. D. New York

ANSWER.—So far as is known, the use of carbon tetrachloride in the textile industry is somewhat similar to its use in dry cleaning and as a detergent degreasing agent in general. Whatever the conditions of use may be whenever 300 or more parts per million of air are present and respired by human beings injury is possible or probable. Carbon tetrachloride vapors breathed into the lungs are far more dangerous than liquid carbon tetrachloride ingested. It is, of course, well known that carbon tetrachloride extensively has been applied for the eradication of hookworm and other parasites. The following types of injury from carbon tetrachloride are known:

1. Dermatitis possibly solely due to the defatting action of carbon tetrachloride.
2. Narcosis. Carbon tetrachloride is similar to chloroform and when concentrations are very high may lead to quick death from anesthetic action.
3. Acute poisoning characterized by inflammation along the respiratory and intestinal tracts. Bronchitis, pneumonia, pulmonary hemorrhage, ocular hemorrhage, gastro-enteritis and intestinal hemorrhage are established features.
4. Delayed poisoning probably associated with fatty degeneration of the liver, the formation or at least the presence of guanidine.
5. Chronic poisoning. A chronic state is poorly defined and if encountered possibly represents only the sequelae of acute damage.

The typical case as encountered in industry presents, in terms of increasing severity, some or all of the following: vomiting, nausea, abdominal pain, fullness in the abdomen, sense of masses in the abdomen, respiratory inflammation, headache, diarrhea, blood in the stools, sleepiness, mental sluggishness, jaundice, tenderness over the liver, convulsions, delirium.

Since carbon tetrachloride is absorbable through the skin preventive measures should embrace protection against this form of entry. Among other preventive measures, the following are suggested:

- (a) Encourage a high intake of calcium as through the drinking of milk.
- (b) Avoid alcoholic beverages.
- (c) Provide closed systems with appropriate vents wherever possible.
- (d) If completely closed systems are not possible positive pressure helmets may be necessary. If concentrations are very high.
- (e) Exhaust systems should be provided with intakes at the floor level rather than near the ceiling.
- (f) Avoid direct skin contact with carbon tetrachloride.
- (g) If completely enclosed systems cannot be provided or if through other measures the concentration of carbon tetrachloride vapors cannot be kept below 500 parts per million of air some less toxic chemical should be substituted for carbon tetrachloride. High boiling point petroleum derivatives such as Stoddard's Solvent while toxic, are less toxic than carbon tetrachloride.

SENSITIVITY TO TOMATOES

To the Editor—I have a patient aged 25 a registered nurse who is afflicted with food allergy. She is hypersusceptible to tomatoes in all forms. Urticaria develops in proportion to the amount eaten. Even on handling the raw fruits as peeling them, she has a red blotch and itching from a splash of juice on the arm or unconsciously touching the face. There is a history of recurrent attacks of facial eczema of a chronic nature in the father. The patient had eczema as an infant from 1 year to 2 years of age. She has dark hair, a dark clear complexion and blue eyes. She discovered by herself shortly after entering nurses training at 17, that she developed hives from tomatoes. She has tried to avoid tomatoes in all forms but frequently gets a little tomato in her food, in the form of vegetable soup broth, meats or salads. What treatment could be used to desensitize her? Are there any canning companies which put out canned vegetable soup or beef broth without using tomatoes? Please omit name and address.
M D, Indiana

ANSWER.—The history here of hypersensitivity to tomatoes is a common one and it is not unusual for urticaria to develop on the eating of the foods as well as by contact with them as in this case.

The treatment is to avoid tomatoes in all forms. If this is carried out for perhaps a year or two, the patient may acquire a slight or considerable degree of tolerance for tomatoes. There is a good chance that she will be able to eat cooked tomatoes, but she will probably never be able to eat raw tomatoes.

As far as desensitization is concerned, the patient can be desensitized in all probability, either orally by administering small amounts of tomato with gradual increases, or hypodermically in similar fashion. However such desensitization is not recommended, as tomatoes can easily be avoided.

An inquiry to Libby, McNeill & Libby brings the answer that their chicken broth contains no tomatoes.

An answer from the Campbell Soup Company brings this reply.

In the blending of Campbell's soups there are many of our kinds which are not prepared by the addition of tomatoes in any form. The Campbell's soups which would be suited to a diet which must be free from tomatoes are:

Julienne	Celery
Chicken	Pea
Consomme	Bouillon
Mutton	Noodle
Asparagus	Printanier

We do know that tomatoes are used in the blending of many soups but we would hesitate to speak specifically about the recipes of other canners.

TREATMENT OF HEREDITARY SYPHILIS

To the Editor—I have under my care a boy of 8 years who has hereditary syphilis. Before treatment was begun his Kahn reaction was four plus. He has been given twenty injections of neoarsphenamine most of them 0.45 Gm each as well as twenty five intramuscular injections of bismuth salicylate. A report from the state laboratory just received still gives this boy a four plus Kahn reaction. Will you please make suggestions for treatment that may give better results than those already obtained. Please omit name.
M D Illinois

ANSWER.—The treatment outlined has been adequate to date and the dosage of arsphenamine ample for a boy of 8 years who, from the letter of inquiry, probably has no active manifestations of congenital syphilis other than the positive Kahn test. It is not unusual for the reaction in the congenitally syphilitic to remain positive for many years even though active symptoms of syphilis are not present. However, asymptomatic neurosyphilis is present in about 12 per cent of such children, and an examination of the spinal fluid is now definitely indicated in a case such as the one cited. The obtaining of a negative spinal fluid report even though the child does not have symptoms attributable to syphilis, such as interstitial keratitis or nerve deafness, nevertheless warrants a series of courses of a bismuth compound. Fifteen injections of a bis-

moth preparation twice a year for at least the next three years are frequently ample in such cases. Even though a satisfactory reversal of the blood reaction is noted at the end of this time and no symptoms are present, the child should have annual examinations to note not only the serologic report but also his general development, mental reactions, and progress in school, as well as any new signs or developments. If the blood reaction remains positive, the bismuth compound should be continued for several years longer. On the other hand, if the spinal fluid is reported positive, thus explaining the persistence of the blood positivity, the intensive use of arsphenamine and a bismuth or mercury compound must be continued. When the character of the spinal fluid report suggests impending juvenile dementia paralytica and routine treatment fails to reverse the reaction to negative, malaria therapy should be given before clinical signs of dementia paralytica appear.

HYPERTROPHY OF MAMMARY GLAND

To the Editor—A girl, aged 11 years fell about six months ago striking her left breast on a hard object. Her parents brought her to me about three weeks later on account of pain and tenderness in the breast. On examination, the right breast showed no development at all. The left breast is symmetrically developed in a diameter of about 3 cm and is moderately tender, the greatest point of tenderness being exactly on the end of the nipple. The nipple itself and the surrounding skin appear perfectly normal. If the other breast were equally developed and there were no complaint of pain and tenderness, one would consider it to be a physiologic development. Since there has been no improvement in the pain and tenderness in the last six months, I am debating the possibility of its being malignant. I find no reference to a cancer of the breast in one of this age and period of development. It would look as though if it were an inflammation it would have shown improvement or gone on to abscess formation by this time. There has been no demonstrable change in size or tenderness in the six months observation. From this meager description would you think the possibilities of cancer great enough to call for removal of a section of this breast for pathologic diagnosis?
M D Illinois

ANSWER.—The possibility of cancer of the breast in the case described is so remote that it may be eliminated with a fair degree of certainty. The age of the patient is the most important evidence against carcinoma, as is also the fact that no extension of the lesion has been observed over a period of six months. It does not seem advisable to remove a section for biopsy.

The condition as described is perfectly consistent with a prepuberty unilateral hypertrophy of the mammary gland. Sometimes a physiologic hypertrophy begins in one mammary gland and is accompanied by pain and tenderness due perhaps to an overactivity of the epithelial and connective tissue elements. After some time a similar activity of the opposite breast appears and renders the diagnosis clear. Although the possibility that an actual injury is associated with the present state cannot be excluded with certainty, it is probable that the injury merely served either to call attention to or possibly accentuate a condition of the breast that was already present. The diagnosis suggested is compatible with the clinical course of the lesion during the time of observation and explains its failure to progress if it were malignant as well as its failure to resolve if it were an inflammatory process of traumatic origin.

PREGNANCY AND DIABETES

To the Editor—Where can I find information concerning the interpretation of a considerable amount of sugar proved to be dextrose and not lactose in the urine of a pregnant patient who showed no sugar in the urine before pregnancy? After a test breakfast of 40 Gm. of available carbohydrate urine specimens collected at half hourly intervals show no sugar until the two and one half hour specimen. Blood sugar at this time is not over 80 mg by the Folin Wu method as is also the fasting blood specimen at 7 a. m. The urinary glycosuria persists on through the entire day but is again negative before the next breakfast. Two and one half hours after the noon and evening meals which are also limited to 40 Gm. of available dextrose the urinary sugar is again at its peak. Blood sugar again two and one half hours after the noon meal is never over 80 mg.
F B WARLOCK B A, Champaign, Ill

ANSWER.—Pregnancy is a complication of diabetes and may activate a potential diabetes. This phenomenon is probably related to the same change in endocrine activity that results in the increase in metabolism during pregnancy, and not infrequently the two disturbances may occur to an abnormal degree at the same time. They may or may not clear up after delivery.

The case described may be exhibiting an alimentary glycosuria which, at the present stage of knowledge must be considered as early or potential diabetes. Should this be the case it would be quite possible for the patient to spill sugar

into the urine during the first hour or two after each meal while still presenting normal blood sugar values when determined in the fasting state or two and one-half hours after the meal.

The other possibility in the case described may be a lowering of the kidney threshold for sugar so that the patient is exhibiting renal glycosuria.

It is suggested that a carbohydrate tolerance test during which urine samples are collected at half-hourly intervals might be helpful in the differential diagnosis. It would then be possible to say whether the patient's kidneys are excreting sugar at a blood sugar level below the normal threshold value of 180 mg per hundred cubic centimeters.

CORRECTION OF PRESCRIPTION

To the Editor—Isn't there some mistake in prescription 2 on page 47 of THE JOURNAL January 5? How can one put 30 Gm of alum in 250 cc. of water and then add alcohol to make 250 cc? That is not the way Dr. Fantus taught us to write prescriptions when I was his pupil back in 1902-1905.

F. P. S. MILLER, M.D., Chicago

ANSWER—There is a serious and obvious mistake in this formula, in which the words to make have unfortunately slipped in instead of "of each." The formula should read as follows:

R Alum	300 Gm
Water	
Alcohol	of each 250 cc

Dissolve the alum in the water and add the alcohol.

M and label. Apply to part subjected to pressure to prevent bedsores.

It is an interesting fact that alum does not dissolve in the alcohol and water equal parts, if mixed previously, but that it does dissolve if the preparation is made according to the directions.

NO TOXIC HAZARD WITH CIGARET LIGHTER

To the Editor—There is a cigaret lighter now on the market made by the Platinum Products Company 521 Fifth Avenue New York which operates by catalysis. In other words to use it one has to draw through a cigaret and thus inhale a certain amount of the vapor of the fluid they call lektrolite. Presumably this fluid belongs to the benzene group. Can you tell me whether the constant use of this lighter is attended by danger to health?

Cecil E. Reynolds, M.D. Playa Del Rey, Calif

ANSWER—This type of lighter has been on the market for about twenty-five years. It will operate with several varieties of highly volatile, low-flash fluids but apparently works best or at least well with Columbian spirit-wood alcohol. By actual test the usual lighter fluids were found not to lend themselves to ready use in this catalytic device. The products of combustion of toxic agents of this general character are rarely so toxic as the unburned vapors. Moreover, the quantity of such vapors arising from a few lightings each hour or day is meager. Theoretically the user of lighters is dealing with a hazardous substance, but the practical danger under usual circumstances is negligible—perhaps more nearly harm free than smoking itself. The high temperature reached by these lighters is of some comparative importance. If one of two cigarets is lighted with the glowing point of another cigaret while the other is lighted with the flame of a catalytic lighter, the latter cigaret on comparison with the former will be found to have become quite soft almost throughout its extent. This is a result of the much higher temperature from the flame. In a measure, this volatilizes or distills the tobacco of the cigaret. To the extent that smoking is harmful, the first puff in connection with a high temperatured lighter is the most dangerous one. This entire matter of injuries from cigaret lighters however, lies in the realm of the nebulous. Proof that such devices should be discarded is lacking.

ROENTGEN TREATMENT OF ACNE

To the Editor—Beckman in 'Treatment in General Practice' states that Parkhurst (1932) reports 84 per cent cures of acne by use of x rays. Please state whether this percentage of cures is generally accepted. Please state also the dosage in such treatments filtration advised and the interval of treatments.

M.D. Mississippi

ANSWER—Eighty-four per cent of cures may be accepted as a fair average in the roentgen treatment of acne vulgaris. MacKee reports 95 per cent of cures in 244 cases. The treatment in all cases was fractional, one-fourth skin unit once weekly, unfiltered, corresponding to 75 roentgens. Other authors report a lower ratio of cures. Michael had 53 per cent in 191 cases after one course of treatment (from ten to sixteen fractional doses) and 85 per cent of cures after a second course. Hazen and

Eichenlaub report 80 per cent. Roentgen therapy must be combined with proper systemic, dietetic and hygienic measures in order to secure the best results. It should not be combined with irritating local treatment, and a proper selection of cases is advisable. MacKee has used both filtered and unfiltered rays in acne vulgaris and states that the therapeutic result was the same. A correct technique and an understanding of the possible dangers is essential. MacKee's book on Roentgen Therapy in Skin Diseases should be consulted.

BILATERAL PHLEBITIS IN PREGNANCY

To the Editor—Is it considered proper by the majority of physicians to advise a therapeutic abortion to an individual who had a moderately severe case of unilateral phlebitis at the last pregnancy? Kindly answer this question pertaining to a patient who had a severe case of bilateral phlebitis as a complication of pregnancy. Please omit the name and address.

M.D., California.

ANSWER—A previous unilateral or bilateral phlebitis is not an indication for therapeutic abortion, regardless of the severity of the complication. While it is true that there is some danger of recurrence of the condition, a therapeutic abortion is not always a harmless procedure and may be just as productive of a new attack of phlebitis as labor at term.

During pregnancy the patient should receive extra care in order to build up her general resistance and she should avoid individuals who have infections of any kind.

During labor every effort should be made to avoid injury and infection. Hence the child should be permitted to deliver spontaneously unless an urgent indication arises for operative delivery.

CHRONIC SINUSITIS

To the Editor—Please give me any information you may have of interest to me in the treatment of chronic sinusitis with high voltage roentgen therapy. I have been suffering with sinusitis a number of years. I had a radical Caldwell-Luc operation done last year without relief, and I am going to have to do something else soon and would greatly appreciate any information you can give me.

M.D. Missouri.

ANSWER—High voltage roentgen therapy has not been of value in chronic sinusitis. If a Caldwell-Luc operation did not relieve the chronic nasal sinusitis the more radical procedure, as carried out in the Denker operation, may give all the relief that is desired. It is essential that every portion of the antral cavity be thoroughly explored and that all diseased mucous membrane, polyps, and so on be removed. The Denker operation offers this opportunity.

RADICULITIS AND TABETIC PAINS

To the Editor—Your answers with regard to radiculitis and tabetic pains (THE JOURNAL, March 30, p. 1187) ignore the use of alcohol for various intractable pains. Surely after the masterful work of Swallow, Labat, Ruth, Woodbridge, James White and others who have followed in their footsteps you must place some confidence in the judicious use of alcohol injection by properly trained men. As a disciple of the late Dr. Goston Labat and after personal observations in a series of 300 cases I have found sufficient merit in alcohol nerve block for these so-called hopeless cases to justify calling attention to the undeniable benefits rewarding technicians using these measures.

The last twenty-five years has been replete with discoveries of various agents for local anesthesia. By a process of elimination it is now conceded that procaine hydrochloride is the least toxic of the group. The impetus given by these discoveries and their use in cases for which general anesthesia would carry a decided risk aided the development of the use of local anesthesia. This necessitated more detailed study of neuroanatomy with the purpose of placing the anesthetic agent accurately, thus minimizing the amount used.

The panorama opens on a new field using local anesthesia for effects that are more permanent. This is being made known frequently by the numerous articles detailing the use of alcohol in combating intractable pains.

In daily practice one sees many patients who may be considered the forgotten or neglected group. These patients frequently resort to morphine addiction, quackery or cult devotion. Cases in which diagnoses are made but in which it has been possible to do little are considered intractable. These patients have run the gamut of medical and surgical procedures to no avail frequently resorting to neurosurgery with attendant shock, high mortality rate and a none too bright post-operative prognosis. Cases of advanced peripheral vascular disease, advanced cancer, painful syphilitic syndromes, angina pectoris and the various protracted arthritides and neuritides fall into this category. The use of alcohol to degenerate the nerve fibers that carry the painful messages to the brain has found its place in medicine. There is no excuse for the folding of hands and curtaining the conscience with the adoption of an attitude of smug satisfaction that everything possible has been done unless due cognizance is taken of therapeutic alcohol nerve block in these conditions.

Book Notices

Physical Diagnosis By Warren P Elmer BS MD Associate Professor of Clinical Medicine Washington University School of Medicine and W D Rose MD Seventh edition Cloth Price \$8 Pp 818 with 342 Illustrations St Louis C V Mosby Company, 1935

This edition presents the subject of physical diagnosis quite completely and in an easily readable form It is surprising how much sound theory slips in without the heavy physics characteristic of some textbooks The special sections on radiology and electrocardiography are excellent for beginners in clinical medicine The general arrangement of the book is satisfactory, with the exception of the section on sphygmomanometry, which rightfully belongs under auscultation of the circulatory system The absence of a bibliography is unfortunate, because interest in medical history is most easily stimulated during the period when the student first learns to use the traditional tools of the great physicians of the past Since the author in his preface expresses gratitude to critical reviewers of the previous editions, it is only fair to point out that certain parts of this book are below the general standard of excellence and could easily be revised upward Thus there is inadequate discussion of the subject of primary hypertension, which is much more important than many other conditions to which special chapters are devoted Venous pressure, spinal puncture and vital capacity are too briefly treated One is particularly disappointed with the bare mention of bronchogenic carcinoma, nowadays a common form of malignant growth The importance of x-ray films in the early diagnosis of pulmonary tuberculosis is not emphasized as it should be even in a textbook on physical diagnosis In the chapters on diaphragmatic pleurisy and pericarditis, no use is made of the classic studies by Capps on pleural and pericardial pain The addition of a few roentgenograms concerning the various types of cardiac enlargement, and a more systematic treatment of the topic of congenital heart disease would strengthen the section on diseases of the circulatory system Little is said about the extracardiac consequences of left auricular dilatation in mitral stenosis Some abbreviation of many paragraphs on clinical pathology would release

space for expansion along these lines. On the whole this work on physical diagnosis deserves its apparent popularity, because it covers a difficult field in a clear, judicious and thoroughly honest manner.

Medical Report of the Glasgow Royal Maternity and Women's Hospital for the Year 1933. Prepared by D. McE. Hart, M.B., Ch.B., F.R.F.P.S.C., Registrar to the Hospital Boards. Pp. 181. Glasgow: Aird & Co. Ltd. 1934.

The eighth annual report of the largest purely maternity hospital in Scotland which has 175 beds shows that during the year 4,595 patients were admitted and 3,198 babies were born in it, 124 per cent were stillborn. Seventy maternal deaths occurred in the hospital giving a death rate of 2.1 per cent. Since the number of abnormal cases in 1933 was 2976, or 64.7 per cent of the total admissions, these figures are not to be wondered at. The hospital is a dumping ground for all the neglected and forlorn obstetric cases occurring in the city and for miles around as far as the Western Isles. The antepartum department has increased enormously: seventy-eight beds being devoted to it in the hospital in addition to an immense amount of work done in the dispensary, the total attendance at the latter being 21,501. In addition the hospital has a home service and, in 1933, 4,510 women were attended in childbirth at their homes, 48,612 visits being made to them. Only 6.6 per cent of the cases delivered at home were abnormal; the fetal mortality was 2 per cent (later given as 1.3 per cent) and the maternal was 0.05 per cent. Hospital cases are divided into two classes: those attending the clinic before delivery and the others. To show the poor quality of the maternal this hospital has to handle, one item may be mentioned. Fifteen women were in such poor condition on arrival that they died before they could be delivered. The patients' temperatures after delivery are divided into two classes: puerperal fever or sepsis and puerperal pyrexia, the latter including those cases in which the fever is of unknown origin or from mastitis, urinary infection, infectious fevers, and so on. The standard of pyrexia is different from that generally used, a patient is febrile if she has a temperature of 100.4 (38°C) or more for twenty-four hours or repeated during the first twenty-one days after delivery, 683 patients came under this classification. A statistical report (there are more than 200 tables) does not lend itself to a critical review, and one must be particularly careful not to use it for comparison with other institutions. The thoroughness with which the statistics have been worked up and the clarity with which the results are presented are commendable and inviting to all heads of obstetric departments and of maternity hospitals. It is much to be regretted that American institutions do not regularly publish similar reports of their work.

Skin Hazards in American Industry. By Senior Surgeon Louis Schwartz, U. S. Public Health Service, and Dr. Louis Tullipan, Professor of Dermatology, New York University. Prepared by direction of the Surgeon General, United States Treasury Department, Public Health Service. Public Health Bulletin No. 215. Paper. Price 10 cents. Pp. 54, with illustrations. Washington: D. C. Supt. of Doc. Government Printing Office, 1934.

Month by month new evidences arise that the commonest practical causes of occupational diseases are to be found in the large group of substances acting on the skin. It is possible that the total list of individual substances leading to industrial dermatoses may exceed 700. This brochure of the United States Public Health Service contributes many new items to the already long list of skin irritants and sensitizers. The title of the publication possibly might lead the reader to expect a general discussion of the skin hazards of all American industry. Instead, it is made up of a series of little related chapters covering investigations of dermatitis in rubber, oil refining, synthetic dye manufacturing, candy making, silk throwsters, linseed oil manufacture, perfume making, and the pyrethrum insecticide industry. The chapters on dermatitis in the rubber industry and dermatitis in synthetic dye manufacturing stand out as superior. All these publications well reflect the strides being made toward precise diagnoses in occupational disease work. Thirty years ago the usual physician may have possessed a knowledge of some twelve items of occupational diseases and among them may have appeared "arsenic pox" as the sole known occupational skin disorder. In contrast these present publications, in the midst

of direct or indirect reference to several hundreds of skin hazards, include the statement that "tetra-methyl thuram monosulphide" is a well known source of skin reactions in hyper-sensitive individuals. The desire for the determination of ultimate causes of disease states is better being fulfilled in connection with occupational diseases than for almost any other division of medicine. These investigations constitute an excellent example of near exactness in diagnosis. Primarily this collection of articles on industrial dermatoses will serve the practical needs of dermatologists, industrial hygienists and plant physicians. But since every scientific worker, whatever his special interests may be, needs stimulation from other fields of endeavor, this interesting and inexpensive governmental publication should be read as it gives an opportunity for insight into the country's most motile branch of medicine—occupational diseases.

Eleventh Scientific Report on the Investigations of the Imperial Cancer Research Fund. Under the direction of the Royal College of Physicians of London and the Royal College of Surgeons of England. Published by the authority of the Executive Committee. Boards. Price 50s. Pp. 177, with illustrations. London: Taylor & Francis, 1931.

The first three papers in this volume are devoted to studies on different strains of filtrable fowl tumors by Foulds. In the first paper, on the growth and spread of six filtrable tumors of the fowl transmitted by grafts, are reported six strains of filtrable tumors transmitted by serial grafts. Although the primary tumor was always situated in the same place (the breast), the secondary growth showed different and characteristic sites of predilection. Furthermore the observations showed differences in the rate and mode of growth, in the proportion of successful inoculations and regressions and especially in the distribution of metastases. The individuality of tumor strains is emphasized and the conclusion is drawn that different tumor strains have distinguishing characteristics of growth and dissemination which are retained indefinitely.

Regarding the histology of these tumors, the second paper, on histologic studies on filtrable tumors of the fowl with special reference to metastatic growths, is especially a study of anomalous features encountered in metastatic growths. The author states that all these tumors showed variations which could not be established by selective transmission. Transplantation of atypical tumors restored them to typical forms. In this manner the temporary nature of the aberrant forms is proved. Conspicuous departures from the usual histologic structure in secondary growths occurred in the thymus concurrent proliferation and abnormal differentiation of the epithelial cells of the gland raised the problem of the capacity for differentiation of normal thymus tissue. This problem was investigated by autoplasmic transplantation of the thymus gland. When thymic tissue is removed from the fowl and re-inoculated into the breast of the same bird there is first a necrosis of the thymocytes. Epithelial cells survive and undergo hyperplasia. In some transplants there is differentiation of squamous epithelium. The potentialities of thymic epithelium are completely realized only under abnormal conditions. Autoplasmic transplantation and tumor invasion lead to a degree of epithelial differentiation not found in the normal gland at any age. In both instances there is destruction of thymic tissue followed by hyperplasia of epithelial cells in an abnormal environment.

Two papers by A. F. Watson, on tar cancer in mice maintained on diets supplemented with fresh liver show the effect of fresh liver in the diet on the susceptibility to tar cancer in mice. These investigations followed the observation that any foodstuff the inclusion of which in the basal diet improved the general condition of the animals also produced the same effect on the rate of growth of the benign and malignant tissues, but ox liver was found to occupy an anomalous position in this respect. The experiments indicated an increased carcinogenic response in tar-treated mice when the diet was supplemented with fresh liver. Larger numbers of animals developed warts and epitheliomas, and benign warts appeared earlier, but the average interval of time between the first tar application and the development of a malignant condition was not reduced. If the administration of liver is discontinued after the first appearance of benign warts there is no difference in the rate of development of malignancy. Since the liver diet does not accelerate

the onset of malignancy it is suggested that the development of benign hyperplasia and the superimposition of the malignant state are conditioned in part, at least, by different factors. The factors in fresh liver responsible for the response are heat stable. A preparation of hog stomachs clinically tested in pernicious anemia induced no increased tumor response in mice. This constitutes evidence against identification of the carcinogenic factor with the hematopoietic factor.

Two studies of E. S. Horning, on micro incineration of the tumors of rodents and on the action of radium on the inorganic structure of tumor cells as shown by micro-incineration give the experience of the Cancer Research Fund with the micro-incineration method of microscopic slides of tumor tissues. These are preliminary reports which demonstrate by means of excellent pictures the fidelity with which the inorganic mineral ash reproduces the most delicate details of cell structure.

Three papers by Crabtree and Cramer dealing with the action of radium on cancer cells and Crabtree's paper on variations of metabolism and radiosensitivity of tissue in bicarbonate and phosphate-buffered mediums, constitute important contributions to the biologic mechanism of the effect of radium on tumor cells. The experiments showed that susceptibility to the action of radium is not a fixed property of a given cell but varies with its environment. Anaerobiosis, hydrocyanic acid and cold diminished the functional activity of the respiratory mechanism, but the effect on the susceptibility to radium is not the same. Anaerobiosis diminished whereas hydrocyanic acid and cold increased susceptibility to radium. In the third paper Crabtree and Cramer conclude that gamma rays have the same biologic effect on cancer cells in vitro as a mixture of beta and gamma rays. In both cases the functional condition of the respiratory system determines the biologic response of the cell, while the glycolytic mechanism is not primarily concerned.

In the next paper (p. 119) Cramer shows the damaging influence of phosphate Ringer solution on the respiratory system of tumor tissue. This effect is shown by direct measurements of carbohydrate metabolism and the increased susceptibility of tumor tissues suspended in phosphate-buffered mediums to gamma radiation.

An important investigation is communicated in the next paper (p. 127) by Cramer. A study of the therapeutic action of radium on spontaneous mammary carcinoma of the mouse showed histologic differences in the reactions to the treatment in radiosensitive and radioresistant tumors. In radiosensitive tumors the reaction begins with invasion of the tumor by macrophages which in turn leads to splitting of the malignant cells affected by irradiation. In radioresistant tumors radium does not produce invasion with macrophages. In view of the results reported, which show that radiosensitivity is not a fixed property of the tumor cells but can be altered by altering the respiratory mechanisms of the cell these results become highly important for since the oxygen supply of the tumor cells is dependent on the stroma the latter must be partly responsible for the property of radiosensitivity. It is shown, furthermore, that the temporary cessation of growth of malignant cells after irradiation is due to a direct action on these cells. A sharp distinction is made between the true recurrences, which are due to the recovery of tumor cells that were dormant after irradiation, and apparent recurrences, which are really the result of a new development of tumor growth due to inadequate irradiation. The bearing of these facts on clinical results is extensively discussed.

The report concludes with two papers by Ludford on the structure and behavior of the cells in the tissue cultures of tumors and the reaction of normal and malignant cells to fat-soluble colored compounds that are insoluble in water. In the first, with excellent illustrations (dark ground photographs of living cells) the appearances of tumor cells are shown that help to distinguish them from the associated macrophages and fibroblasts. In the second paper a new method of staining fatty substances in living cultures is described.

Ludford's results suggest that although malignant cells are readily permeable to fat soluble substances they are less permeable to water soluble compounds than normal cells. The tentative explanation is put forward that the plasma membrane of malignant cells is relatively rich in fatty substances.

These researches are prepared and presented with the usual thoroughness and scientific accuracy of these authors. The illustrations are magnificent. The report adds further important knowledge to the metabolism and cytology of tumors and to radiation effects on tissues.

The Doctor's Son and Other Stories By John O'Hara. Cloth. Price \$2.50. Pp. 204. New York: Harcourt, Brace & Company, 1935.

The author of this novel is the son of a physician. In his book "Appointment in Samarra" he revealed the tremendous influence of his boyhood in a medical home. The present volume is a collection of his sketches, many of which appeared in the *New Yorker*. The opening story is however, a long story not previously published, which recounts the life of the doctor and of the doctor's son during the great influenza epidemic. It is medical realism to the highest degree and it is offered in modern diction, showing the influence of Hemingway. Physicians are certain to find this story fascinating, humorous, tragic, exciting.

Dietetics for the Clinician By Milton Arlenden Bridges, S.B., M.D., F.A.C.P., Director of Medicine, Department of Correction Hospitals, New York. Foreword by Herman O. Mosenthal, A.B., M.D., Director of Medicine at the New York Post-Graduate Medical School, Columbia University, New York. Second edition. Cloth. Price \$10. Pp. 670. Philadelphia: Lea & Febiger, 1935.

In the presentation of a second edition of this work, errors in the first volume have been corrected. New subject matter has been added and all of the sections have been brought down to date. The book provides a tremendous amount of tabular data including reliable analyses of the common and proprietary foods. There are also tables giving the latest data concerning alcoholic beverages. The volume has been prepared by the author with the assistance of a considerable number of competent clinicians and is one of the most immediately practical and useful volumes in dietetics available to the physician.

Medicolegal

Hospitals Liability for Death of Delirious Patient—The deceased entered the Williams Sanatorium, Inc., an institution operated for profit, for the purpose of being treated for a small cancer on his hip, Nov. 14, 1932. The treatment, rendered by Dr. Boyd Williams, the owner of the institution, was painless and Brase apparently suffered no ill effects therefrom although he remained at the hospital. In the evening of November 15, however, Brase was found, partly dressed, attempting to get out on a porch of the hospital. The nurse who apprehended him testified that he was slightly delirious but that she had little difficulty in persuading him to return to his bed. He talked irrationally and made several attempts to rise from his bed but was restrained by two nurses. Shortly after his return to bed he became highly excited, and the two nurses testified that it was necessary for them to apply "restraints" in order to keep him in bed. Dr. Williams was not then at the hospital and when informed over the telephone of the patient's condition he advised the nurses to use "restraints" and to administer a hypodermic of strychnine. The "restraints" used consisted of heavy ticking which was placed across the patient's knees, the ankles were fastened to the foot of the bed, and the arms strapped to the sides of the bed. One of them being fastened by a handcuff. One hypodermic of strychnine was given the patient but his delirious condition continued. Another hypodermic was given a short time before he died. He fought strenuously to free himself of the "restraints" until about 4 o'clock on the morning of the 16th of November, when his struggles ceased and at about 6 o'clock he died. The executor of Brase's estate brought suit against the Williams Sanatorium, Inc. and another. From an order denying the defendants' motion for a judgment notwithstanding the verdict, the defendants appealed to the Supreme Court of Minnesota.

At the time Brase entered the hospital he was given a physical examination by Dr. Williams, who testified that Brase was in good health. Another physician who had examined him shortly before his entrance to the hospital came to the same

conclusion An autopsy showed the vital organs of the body to be normal, with the exception of the lungs, which were congested Two physicians testified that death was caused by exhaustion due to overexertion as evidenced by the congested condition of the lungs, and that in cases of patients in an excitable or delirious condition the administration of strychnine, a stimulant, is improper A sedative should have been administered, according to the witnesses Williams himself testified that the use of "restraints" was not improper in such a case and that the cause of death was not exhaustion He was corroborated in this by another physician The jury might well have found said the court, that the delirium and excitability of the patient, aggravated by the improper administration of strychnine, caused the patient to exhaust himself in his struggles against the bars which held him to the bed The evidence was sufficient to sustain a finding that the treatment administered was not proper practice and that it caused Brases death

The appellants contended that the trial court erred in admitting evidence that Dr Williams had been convicted of practicing medicine without a license in the state of Minnesota The practice of medicine without a license said the court is made a gross misdemeanor under section 5714, Minn's Minnesota Statutes, 1927, and under section 9948, evidence of the conviction of a crime is admissible for the purpose of affecting the weight of a witness's testimony A gross misdemeanor being a crime pointed out the court, the evidence complained against was admissible Finding no error in the record the judgment of the trial court against the defendants was affirmed —*Brase v Williams Sanatorium, Inc., et al (Minn.)*, 256 N W 176

Wills Criteria of Testamentary Capacity—In law, said the Supreme Judicial Court of Maine every mind is sound that can reason intelligently in the particular transaction and every mind is unsound that cannot so reason The law does not undertake to test the intelligence and define the exact quality of mind which a testator must possess Soundness is a matter of degree That a man may make a valid will, it is not necessary that the greatest mental strength shall prevail The essential qualification for making a will is a sound mind "Sound mind," within the statute of wills, continued the court comprehends ableness enough to recollect property and beneficiaries, and conceive the practical effect of the will The expression does not mean a perfectly balanced mind A mind naturally possessing power, not unduly impaired by old age or enfeebled by illness, or tainted by morbid influence, is, in legal contemplation, a "sound mind."

In this particular case, the testatrix was advanced in years But said the court stage of life and resultant weakness of body do not necessarily deprive one of the right to make a will Neither age nor bodily disease is of itself, a disqualification Intellectual and physical weakness, with partial failure of mind and memory, is said not to be solely an indication of inability to make a will Although a testatrix be old and infirm, she may competently will, if she then had intelligence enough to understand correctly what she was doing, and did deliberately, what she meant to do Hallucination, temporary in nature, is not per se insanity When a hallucination has become permanent, it is to be deemed insanity general or particular, according to the nature of the delusion To invalidate a will an insane delusion must be operative on testation A person whose mind is affected by such a delusion, however unreasonable and absurd, may make a valid will, provided the delusion is not of influence To affect its soundness, the will must be the direct offspring of delusion controlling the mind Except so far as it may tend to show the quality of the testator's mind at the time of executing the will, the condition of his mind before or after that time is unimportant If he was then rational and acting rationally, or, in popular phrase, knew and understood what he was about, the will is valid. Although fixed insanity has been established, it may be shown that execution of the will was during a lucid interval There may, in a case of senile dementia, be such a thing as a lucid interval, during which the person is qualified to will The will of the testatrix in the present case was upheld by the Supreme Judicial Court of Maine.—*In re Loomis Will In re Mitchell et al (Maine)* 174 A 38

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

*Pruritus Ani. New Treatment. N J Simmons Boston—p 53

Diabetes and Diverticula of the Duodenum.—Thorning and Root report diverticula in the duodenum in two diabetic patients with previous operation for gallstones. The possibility that inflammation in or about such diverticula can by extension cause chronic pancreatitis and diabetes was not demonstrable. The persistence of digestive symptoms after a gallstone operation may occasionally be due to such diverticula. The downward course in one patient over a period of five years may be attributed to several causes, such as cardiovascular disease, a possible gallstone in the common duct, a neoplasm and the results of the duodenal diverticula. In the other patient the authors have no suggestion that the diverticulum is responsible for symptoms or pancreatitis. In attempting to evaluate the significance of the diverticula, their frequency without serious symptoms as well as the complications produced by them must be borne in mind.

Glycosuria and Lactosuria of Pregnant and Lactating Women.—Brock and Hubbard outline a method capable of demonstrating lactose in concentrations as low as from 5 to 10 mg per hundred cubic centimeters and discuss the results of its application to a series of urine specimens from pregnant, lactating and normal women. Lactose is usually absent from the urine of normal women, although occasionally traces, probably of alimentary origin may be found. Lactose is almost always present in increased amounts in the urine of lactating women during the first days after parturition. It can be demonstrated at least in some instances, months after delivery. The lactosuria probably results from an overflow of active mammary glands. Lactose is present in small amounts in the urine of a large proportion of pregnant women. Sometimes it can be demonstrated in the early months of pregnancy but is not always found even in the days immediately preceding parturition. In the opinion of the authors this lactosuria is caused by activity of the mammary glands. Dextrose was present in the urine of lactating women in slightly greater concentration than it was in the urine of a comparable series of nonpregnant nonlactating women, but the difference was small and probably not significant. Sugar of this type was present in quite large amounts in the urine of pregnant women. This glycosuria did not appear to be clinically significant. Positive reactions with Benedict's qualitative reagent were due to dextrose in the urine

from normal subjects, to lactose in the urine from lactating women, and in a majority of instances to dextrose in the urine of pregnant women.

Pruritus Ani.—Simmons classifies the etiology of pruritus ani into pathologic changes in or about the rectum and anus, infections of the skin or mucous membrane, systemic diseases causing perirectal itching and idiopathic or essential pruritus ani. The author has employed a solution of 0.5 per cent of nupercaine, 1 per cent of phenol and 10 per cent of benzyl alcohol in almond oil. He has used this solution with excellent results in twenty cases, freedom from pruritus lasting from four to six months. After the anal region has been cleansed, 5 cc of the solution is injected under the itching area. The posterior quadrant is injected on the first visit and the lateral and anterior quadrants on subsequent visits. Pooling of the oily solution, infection or eczema may lead to sloughing and a prolonged healing period.

Blood Phosphorus During Development and Healing of Rickets.—Warkany's experiments on rats show that a single large dose of viosterol does not bring the inorganic blood phosphorus back to normal if the animals are kept under the original rickets-producing conditions. After ten days, when complete healing of the lesions of the bones is shown by roentgen examination, the inorganic phosphorus has increased to from only 50 to 60 per cent of the normal value for phosphorus in rats. This value, approximately 4 mg, then remains unchanged for weeks, in spite of the continued rickets-producing diet. This is in contrast to the results of experiments in which rats on a rickets producing diet showed a decrease of phosphorus to about 2 mg. A method is described, based on the principle of Kuttner's molybdic acid-stannous chloride reaction which can be performed with 0.05 cc of serum or plasma. A single determination of phosphorus has little significance in the analysis of experiments or in the treatment of clinical rickets.

Leukocytes in Ambulatory Children with Tuberculin Reactions.—Smith examined periodically the white blood cell count with the supravital technic in an endeavor to discover any significant alterations produced by manifest disease in twenty-three ambulatory patients having the childhood type of tuberculosis. The results were compared with similar blood counts of normal children. The age periods extended from infancy to 4 years and from 4 to 13 years. The peripheral blood of the ambulatory child who was already infected but whose contact with the source of exposure had been broken differed except for minor alterations, in no wise from the normal. A lymphocytic increase constituted the prominent feature. The blood count does not perform the function of a diagnostic test in tuberculosis, but in periods of suspected clinical activity it does supply information of a more precise nature of the pathologic process than can be obtained from the complaints of the patient, the physical examination or the roentgenogram. The cellular changes were most pronounced during activity in the younger child. The alterations noted in the blood smear differed only in degree from a group of fatal cases of tuberculosis in young children. The author suggests a

tentative monocytic percentage and monocyte-lymphocyte ratio as a guide to early manifestations of activity. It is still problematic whether a comparison of the changes in the blood before and after administration of tuberculin can be utilized to represent the state of focal activity. These changes may possibly serve as an indication of the immunologic status established by the primary infection and to portray the character of the cellular response in the event of later reinfection.

Snake Venom for Control of Bleeding in Thrombocytopenic Purpura.—Of eight patients treated by Greenwald with splenectomy and repeated transfusions during the years from 1928 to 1932 inclusive, two died of cerebral hemorrhage and one of postoperative shock. Three patients were treated in 1933 with intradermal injections of diluted snake venom, active bleeding was controlled rapidly in every case. No further bleeding occurred in two children, one patient, who was almost exsanguinated on admission to the hospital and who did not receive the injections regularly, manifested oozing from the nasal mucous membranes six weeks after the beginning of the treatment.

Effect of Scarlet Fever on Immunity to Diphtheria.—Kojis and Crug state that of 219 hospitalized patients having scarlet fever eight lost their immunity to diphtheria as determined by the Schick test. The presence of complications, the severity of the infection and the age of the patient had no effect on the loss of immunity to diphtheria. Of the group of patients to whom antitoxin had been administered, 16 per cent lost their immunity to diphtheria as compared with 6 per cent of the group of patients to whom no antitoxin was administered. Every patient having scarlet fever should be given a Schick test during his convalescence, and until it has been demonstrated that a positive reaction to the Schick test may revert spontaneously to a negative one following an attack of scarlet fever, the patient should be immunized if the reading is found to be positive.

- Ovarian Pregnancy.** W. C. Thro. New York—p. 457.
- Intestinal Complications from Radium and Roentgen Irradiation.**—Jones points out that in 520 patients having cervical carcinomas, who received radiation therapy, there have been seven known cases of benign stricture of the intestine causing obstruction which might easily have been construed as, or confused with metastatic deposits. In five the obstruction was in a movable segment of the sigmoid and in two in the small intestine. Since similar methods of therapy are in general use, it seems probable that the incidence of the lesion is greater than is surmised, and, if similar cases have been attributed to metastasis in the past the mortality statistics relating to metastasis from cervical carcinoma are open to question. The intestinal obstruction developed in the seven patients from eight months to eight years after radiation therapy for cervical carcinoma. If the condition actually is a benign stricture caused by irradiation, it is obvious that additional roentgen treatment would only aggravate the condition and hasten the end. Therefore a patient in whom unusual abdominal symptoms are present, particularly if they simulate intestinal obstruction, may have a stricture of the intestine and may be restored to normal health by resection of the lesion. Before attributing this disability to metastasis thorough reexamination by sigmoidoscopic and roentgenographic studies should be made to eliminate the possibility of this curable complication. Strictures in the small intestine are difficult to visualize unless the obstruction is practically complete. Barium in large amounts is inadvisable, and therefore exploratory operation is warranted especially in patients in whom there is no evidence of recurring carcinoma in the pelvis.
- Pneumococcal Pelvic Infection in Adults.**—King states that the clinical manifestations of pneumococcal pelvic infections in adult women are quite constant and characteristic. There is often a previous indisposition usually associated with the symptoms of an infection of the upper respiratory tract. The invasion of the peritoneum is characterized by its sudden onset with chills or 'chilly feelings'. The pain is sudden, severe, and

located in the lower part of the abdomen. The pulse rate is high at first, but with early localization the rate drops out of ratio with the temperature. A leukocyte count of 20,000 or more is usual with a polymorphonuclear count of 90 per cent or higher. With a fulminating spread the evidences of general peritonitis are present. The distinguishing point is the rapid formation of pus, which takes place earlier and in far greater quantity than in peritonitis from appendicitis or other causes. The author divides pneumococcal pelvic infections in adult women into four groups. 1 The pelvic abscess in which the infection, having become walled off early, remains confined to the pelvis. 2 The generalized peritonitis in which the entire abdominal peritoneum becomes the abscess sac. 3 An infection confined to the tube and ovary. 4 Puerperal infection following either abortion or labor at term. Patients in the first group recover promptly on draining of the abscess by posterior colpotomy. The cases of generalized peritoneal infection of the second group have a high mortality. Until the clinical and laboratory features have been more carefully elaborated on which an early diagnosis may be made, there is little hope of improvement in the present mortality. The author believes that it is reasonable to expect that prompt drainage would result in the infection remaining localized in the pelvis and that it would spread to the general peritoneum in fewer cases. Colpotomy is such a simple and safe operative procedure that there is little that can be urged against it. In the presence of a well developed general peritonitis, adequate drainage is the only hope.

The Cold Test in Pregnancy—Randall and his associates determined the reactions to the cold test of Hines and Brown, numbering 130, on 104 pregnant women. The only values that they have for comparison deal with the general problem of hypertension. They feel that the hypertension associated with toxemia of the latter months of pregnancy is related to a toxin which affects the whole maternal organism and that pre-eclamptic toxemia is associated with spastic constriction or with contraction of the arteriolar system. This constriction or contraction may be related to a particularly reactive vasomotor system. It is possible that a pregnant woman who manifests an exaggeratedly reactive vasomotor system in response to the cold test is more likely to suffer from toxemia of the latter months of pregnancy. Toxemia has not developed in any case in which the response to the cold test has been persistently normal and a hypertensive reaction has been demonstrated in all cases in which toxemia has developed. Of the patients who have manifested a definitely exaggerated reaction, 33 per cent gave the usual signs of toxemia in the latter months of pregnancy.

Effect of Pregnancy Urine on Ovary-Stimulating Potency of Hypophyses—Goodman observed that, in rabbits, the intravenous injection of ether-extracted human pregnancy urine increases the ovary-stimulating potency of the hypophyses of normal adult male and female rabbits and of spayed adult female rabbits. Contrariwise, in rats the subcutaneous administration of ether-extracted human pregnancy urine decreases the ovary-stimulating potency of the hypophyses of adult male and female rats and does not change the potency of the hypophyses of castrated adult male rats. In a small series of spayed female rats the subcutaneous administration of ether-extracted human pregnancy urine increases the ovary-stimulating potency of the hypophyses. Spaying without treatment with urine increases the ovary-stimulating potency of the hypophyses of both rabbits and rats. The ovary-stimulating potency of hypophyses of normal adult male rats is greater than that of adult female rats. After gonadectomy the increase in potency is greater in the females. The present experiments suggest that in the rabbit the action of human pregnancy urine on the hypophysis is partly indirect through the gonads and partly direct on the hypophysis itself. The influence on the hypophysis

is similar to the effect of gonadectomy. In the rat on the contrary the effect of pregnancy urine on the hypophysis appears to be an indirect one only through the gonad. This gonadal influence differs from that occurring in the rabbit in that it is presumably due to the inhibitory action of estrogenic substance or the testis hormone.

Diagnostic Value of Urine Diastase—Foged believes that the diastase examination gives information in acute disorders of the pancreas. In the differential diagnosis, when it is a question of stone in the common bile duct the positive result of the test favors this disease so strongly that at present there is no other laboratory examination which gives such sure information. There is sufficient reason to undertake diastase examinations in the following cases: (1) in all uncertain abdominal cases, especially when a pancreatic disease is suspected, (2) in diseases of the gall passages, (3) in diseases accompanied by icterus and (4) in postoperative complications, especially following operations adjacent to the pancreas. The result of a diastase analysis will not give the diagnosis immediately. The circumstances are such that a diastase reaction evaluated with understanding and linked with the clinical picture often gives a strong point for or against a definite diagnosis. The diastase examination is a laboratory examination that is simple, quickly made and inexpensive.

Jelks' Operation for Rectal Stricture—Bacon and his associates discuss twenty-four cases of rectal stricture in which Jelks' operation was performed. The patients were symptomatically improved. Toxic phenomena were diminished and an increase in the percentage of hemoglobin and the number of

red cells was noted. An increase in weight was observed in fifteen cases. At the end of nine weeks the average increase was 5½ pounds (26 Kg.), at six months 9 pounds (4 Kg.), at ten months 10 pounds (45 Kg.), and at fourteen months 12 pounds (55 Kg.). Diathermy was used in five cases without apparent change. The patients who did not return to the clinic for periodic dilation showed a greater degree of subsequent contracture. Similarly, those cases in which the preoperative narrowing was marked were more prone to contract sooner and to a greater degree. Likewise the longer the stricture the greater the contraction. Patients in whom drainage continued for a period of three weeks or more showed a lesser degree of subsequent narrowing. The method consists of an anteroposterior incision, 1½ inches in length, made on either side lateral to the anus and just beyond what would correspond to the margin of the outer fibers of the external sphincter muscle. Each incision is carried to the under surface of the levator, and a closed hemostat is inserted through this muscle, opened and then withdrawn. With the finger in the rectum as a guide, a scalpel is introduced through this opening and the hard fibrous tissue on each side is severed up to and just beyond the upper limitation of the stricture. The incision is carried round the lateral sides of the rectum almost for its total circumference, except for about 1 inch posteriorly and from 2 to 2½ inches anteriorly. In twenty one of the twenty four cases a posterior incision was made through the entire length of the stricture for a depth of approximately one fourth inch (stricturotomy). This was done because the lumen of the stricture was not sufficiently large after severance of the extravisceral or perirectal fibrosis. Three cases in which the posterior incision was made were complicated by hemorrhage and necessitated the use of a cautery. Each lateral wound is packed from its apex downward with iodoform gauze, and through the lumen of each stricture a small rubber tube is inserted surrounded by petrolatum gauze.

Fractures of Neck of Femur—Snodgrass suggests the following technic for the treatment of fresh fractures of the femoral neck. Age and condition permitting, the patient is placed on a fracture table with a pelvic bar, complete anesthesia is induced and strong downward traction is applied to the injured extremity. As this traction is applied, the extremity should be in complete extension at the hip joint and in midposition between abduction and adduction. After traction has been applied, the extremities should be measured and compared as to length. The main variable factor in fracture of the hip is the direction of displacement of the head fragment. The distal fragment may be readily pulled down under anesthesia, preceded by different methods of traction, and can be placed in any position, by virtue of the fulcrum action of the iliofemoral ligament. If the direction of the head fragment is found to be in its usual position at a right angle to the acetabular rim, outward rotation of the extremity by using the foot, followed by full adduction, will reduce the fracture and obtain the final position. Strong downward traction must be maintained until the extremity reaches full adduction. If the head fragment is rotated upward and backward, as it commonly is, because of pressure from the iliofemoral ligament made tense by the weight of the femur a different maneuver should be executed. The extremity is placed in full adduction, then externally rotated and finally pulled downward. At the same time, while an assistant holds the extremity in full extension and moderate adduction, the operator may lift upward (anteriorly) and outward on the thigh. The extremity should be in full extension of 180 degrees when the lifting is done, and the foot and ankle should be held down as the thigh is lifted upward and outward. Whichever maneuver is used, the final position should be full extension, full adduction to a point where the sagittal midline of the body may be projected downward through the knee joint and full external rotation. The final position is followed with a plaster spica from the toes to above the pelvic brim. Success or failure depends on accurate reduction. The fragments must be brought in contact end on, even though complete apposition of both fractured areas is not obtained. The manipulative result should be checked at once by roentgenograms taken through the plaster cast. The operator has at hand two clinical tests of some value in determining the amount of reduction obtained. First, by inspection

one may note whether or not the leg rolls into extreme external rotation, after it has been moved into adduction. Second, by palpation one may note the tenseness of that portion of the fascia lata between the great trochanter and the brim of the pelvis, comparing it with the same area on the well side when the assistant places the well leg in a corresponding position. These two tests are not diagnostic of full reduction but serve only to show that the fragments are end on. The second main factor to be observed is the elimination of all muscle pull. The adduction-external rotation method presented depends entirely on the end-to-end reduction of the fragments. This is where the emphasis must be placed if surgery is to make a real advance in the treatment of these cases.

Progeny of Tubercle Bacillus S. J. Maher Shelton Conn.—p. 350

Lesions Following Inoculation with Bacillus Calmette-Guérin.—Feldman prepared glycerin-peptone broth cultures using a strain of Bacillus Calmette-Guérin, obtained from Calmette in 1930 and grown for twenty generations subsequently on an egg glycerin medium, to inoculate six rabbits intravenously and four guinea-pigs subcutaneously. One of the rabbits died ten days after inoculation and the other five were killed 174 days after inoculation. Numerous and striking focal lesions morphologically like tubercles, were found in the lungs of each of the five rabbits. Attempts to culture acid-fast bacteria from the lesions of the lungs were futile, although bacteria of this character were readily demonstrable in appropriately stained sections of the lesions. Emulsions prepared from lesions from each of the five rabbits failed to produce demonstrable lesions in other rabbits or guinea-pigs, and attempts to repeat the results in later experiments failed. These results indicate that the Bacillus Calmette-Guérin in the lungs of rabbits may at times produce numerous and extensive tubercle-like lesions.

Tuberculosis as Causative Factor in Addison's Disease.—Colton states that of the eight cases of Addison's disease in which death occurred and postmortem examinations were made at his institution, all but two presented tuberculosis of the adrenals. The two exceptions showed amyloid degeneration of both adrenals. At necropsy, tuberculosis of the adrenals was present in twelve cases, clinical symptoms of Addison's disease being absent in six. In all of the eight cases tuberculosis was present elsewhere in the body, principally pulmonary although three showed only arrested or healed pulmonary disease and one a moderately advanced slightly active pulmonary lesion. Genito-urinary tuberculosis was a major condition in two. The complications in these cases were five gastro-intestinal and two bone and joint tuberculosis, two tuberculous empyema, three amyloid disease of the liver, spleen and kidneys and one hyperthyroidism. Clinically all eight presented a typical Addison's syndrome, including extreme weakness, gastro-intestinal pains (usually cramps), nausea, vomiting, headaches and loss of weight. Low blood pressure (from 90/70 to 124/80) was present in six. Unfortunately, studies of blood pressure were not complete. Two cases were not recorded. Bronzing of the skin and mucous membranes was present to a varying degree in five. There were visionary disturbances in three. Sudden collapse occurred at death in four. One showed absent reflexes of the lower limbs and one numbness of the arms and hands.

Experiments on Filtrability of Tuberculo-virus.—Summarizing their observations based on the examination of 209 guinea pigs and seventy-seven cultures, Piasecka-Zeyland and Zeyland report that their attempts to substantiate the quoted methods of demonstrating the filtrability of the tuberculous virus have given them only negative results. Comparing them with the results of other authors they are certain that the

problem of filtrability in tuberculosis cannot be decided. A critical review of the literature on this question shows that among the adherents every worker obtains positive results exclusively by his own technic and none of the described methods have given positive results in the hands of other authors not belonging to the same school, in other words, these experiments are marked by lack of ability of reproduction, and that is the main obstacle to the general acknowledgment of a fact in experimental science. The problem of the filtrability of tuberculous virus demands still further investigation with the application of new methods.

Secretion of Mucus and Acid by Stomach.—Necheles and Coyne measured the gastric secretion of visible mucus after fasting and following the injection of pilocarpine in thirty-seven normal persons and in twenty-four patients having duodenal ulcer. The amount of visible mucus in the stomach after fasting was found to be greater in normal persons more than 40 years of age than in those less than 40. This increase with age did not take place in patients having ulcer. After the injection of pilocarpine normal persons showed an increased secretion of visible mucus, while patients having ulcer (non-drinkers and drinkers of alcohol) do not show such an increase. Normal persons who drink alcohol show a decreased secretion of mucus after the injection of pilocarpine.

Estrogenic, Luteal and Gonadotropic Hormones in Hemophilia.—The observations of Chew and his associates on two hemophilic patients for ten and thirteen months, respec-

tively, while receiving no specific therapy and while receiving preparations of estrogenic substance by mouth and subcutaneously, the hormone of the corpus luteum intramuscularly and the gonad-stimulating hormone from the urine of pregnant women subcutaneously, indicate that persons with hemophilia have no lack of estrogenic substance in their urine and, although it does not necessarily follow, probably have no deficiency of this principle in their blood. Their observations fail to substantiate the theory that an absence of this hormone is responsible for the impaired coagulability of the blood. Conversely, they have been unable to alter the characteristic fluctuations of the prolonged coagulation time of the blood in hemophilia by the administration of estrogenic substances. The frequency with which increases in the coagulation time of the blood were associated with a demonstrable amount of the gonadotropic factors in the blood and the somewhat increased blood coagulation time in one patient while he was receiving follutein, an anterior pituitary-like gonadotropic substance, and after exposure of the pituitary region to stimulating doses of roentgen rays are observations which could be construed to indicate that the gonad-stimulating hormone of the anterior pituitary gland may contribute an adverse factor to blood clotting in hemophilia. However, the absence of demonstrable amounts of the gonadotropic factor in the blood of persons with hemophilia while a prolonged coagulation time was maintained argues against the essential importance of this factor in influencing the coagulation time. None of the various hormones exerted any fundamental influence on this sex-linked hereditary disorder of blood clotting.

The Electrocardiogram in Myocardial Infarction — Barnes endeavors to integrate the clinical pathologic and experimental observations published on coronary occlusion. The site of the acute infarct in the left ventricle and not the vessel supplying the area determines the character of the electrocardiographic changes that will result. Experimental destruction of areas in the anterior portion of the left ventricle produces electrocardiographic changes that are different from those obtained by the injury of similar portions of the posterior portion of the heart. These electrocardiographic changes are a deviation of the RST segment. The preponderance of evidence is against the interpretation that deviation of the RST segment in acute myocardial infarction depends on the development of an additional factor of cardiac failure. Experimental and clinical evidence indicates that the RST deviation observed in the electrocardiogram after infarction is the primary event and that changes of the T wave are sequential and secondary to that deviation. Typically developed Q_1 and Q_2 patterns of infarction have a definite diagnostic and localizing value, and the combined consideration of the Q and T patterns will yield more information in the diagnosis than will either pattern considered alone. Under proper conditions the presence and situation of acute infarction can be predicted almost always from the electrocardiographic changes that develop. Presumptive evidence of previous occlusion may be obtained from the appearance of inverted T waves observed months after the acute occlusion. These T waves are the coronary T waves of Pardee and are chiefly characterized by their depth and the character of the RT intervals that precede them. The reciprocal relation of T_1 and T_2 , in which as one becomes more inverted the other becomes more positive is important evidence of preceding acute occlusion. Not all RST changes observed in angina pectoris, coronary sclerosis or myocardial fibrosis are to be ascribed to coronary disease, because many of these cases present no significant electrocardiographic changes. Neither the presence nor the site of chronic dystrophic fibrosis of the myocardium is disclosed by any electrocardiographic change described to date. Electrocardiograms with low voltage of the QRS complex in all leads after acute infarction probably increase the gravity of the prognosis. The development of highly characteristic electrocardiograms of the T_1 or T_2 type after acute infarction seems to indicate a more favorable prognosis than do atypical electrocardiograms. Electrocardiographic changes signifying acute infarction may appear as early as from one to two hours after acute coronary occlusion, and the electrocardiogram may not return to normal in some instances for two or three years or more.

Hodgkin's and Other Diseases of Lymph Nodes.—

Potter divides pathologic conditions of lymph nodes into two groups: those secondary to disease elsewhere in the body and those in which lymphoid tissue is the structure primarily involved. The first group includes simple hyperplasia, acute and chronic inflammation and metastatic tumor infiltration. The second group includes the leukemias and reticulo-endotheliosis, the various types of lymphosarcoma, reticulo-endothelial sarcoma, endothelioma and Hodgkin's disease. In all diseases primary in lymph nodes reticulo-endothelial tissue of any part of the body may be involved. These diseases involve primarily the undifferentiated reticulum cells, those cells which show no differentiation into either sinus endothelium or phagocytic cells. Leukemia is the result of a stimulation of the hematopoietic function of reticulum cells. There is an abnormal proliferation of reticulum cells, most of which develop rapidly into hemocytoblasts. Sarcoma of reticulo-endothelial tissue also results from abnormal proliferation of undifferentiated reticulum cells. There is an entirely unsuccessful attempt to form mature cells, although there may be slight differentiation into hemocytoblasts, endothelium of sinuses or simple reticulum cells. In Hodgkin's disease there also is a proliferation of reticulum cells. There is a development of reticulum cells along all lines normally followed plus the formation of various types of abnormal cells. After proliferation the reticulum may remain as normal syncytial cells; they may become more completely fused and solidly packed and resemble endotheliomatous tissue; they may increase in size and develop more hyperchromatic nuclei while still retaining their syncytial character and resemble somewhat the cells of retithelioma; and they may develop into the specific type of mononuclear or polymorphonuclear cells that are characteristic of Hodgkin's disease. In addition they may develop into normal hemocytoblasts, normal fixed or free phagocytes, or fibroblasts. There is always a protean type of cellular differentiation. Hodgkin's disease is always characterized by pleomorphism of cells. The microscopic appearance of Hodgkin's disease depends on the relative predominance of certain developmental tendencies. A definite diagnosis of Hodgkin's disease cannot be made without the presence of specific Hodgkin cells. Hodgkin's disease may be subdivided according to the predominant cells (endotheliomatous, reticular, cellular, sclerotic). If there is no cellular variety and if Hodgkin cells are absent, the condition must be called "endothelioma," lymphosarcoma or reticulum cell hyperplasia. Hodgkin cells are occasionally absent from individual nodes, even when present in the majority. Since all the diseases primary in lymph nodes may show reticulum cell proliferation, the presence of hyperplasia of these cells alone is insufficient evidence for making any specific diagnosis. In each disease primary in lymph nodes there is development along a specific line. In rare atypical cases the stimulus ordinarily producing a specific histologic change may lead to the formation of the type of tissue ordinarily produced by another cause and associated with another disease. The microscopic pictures of all diseases primary in lymph nodes may, in rare instances, in individual nodes, be identical with the exception that Hodgkin's cells are never found except in Hodgkin's disease. Hodgkin's disease, the sarcomas arising from reticulo-endothelium and the leukemias and aleukemias represent three distinct entities.

Resection of Large Fractions of Renal Substance—

Allen and his co-workers subjected eight dogs, aged from 5 to 6 months, to resection of large fractions of renal substance. The largest fraction was not less than three-fourths. After an interval of several months the degree and nature of the hypertrophic response in different animals of a litter were made.

Transitory increases occurred in the concentration of blood urea following resection but as little as one fourth of the renal substance was capable of maintaining a normal concentration. Readings of the blood pressure (indirect and direct) were normal. In one animal nearly three fourths of the renal substance (728 per cent) was removed at one operation, and the animal survived. In another animal somewhat more than three fourths of the renal substance was removed in two stages by waiting for compensatory hypertrophy to occur in the interval, and the animal survived. Evidence is presented which indicates that the larger the proportion of total renal substance resected (but not in excess of approximately 70 per cent) the greater is the relative hypertrophy that occurs, both in terms of the mass of the kidney and in terms of the size of the renal corpuscles and tubules. These observations suggest that compensatory renal hypertrophy is a physiologic or work reaction.

Treatment of Atrophic Arthritis—Lamb and his associates state that there is no definite evidence that atrophic arthritis is caused by any one specific type of streptococcus. The evidence seems to indicate that the disease results from the effect of different types of streptococcus localized in varied foci of infection. It is likely that the reaction in the joints to the products of these organisms is an allergic one. In support of this it has been demonstrated that cases of atrophic arthritis will react with a positive skin test to filtrates prepared from the strains of streptococci isolated from their own foci of infection. It is to be emphasized that bacterial filtrates and not vaccines are to be prepared for skin test and therapy. Of the patients having atrophic arthritis treated by desensitization to autogenous streptococcus bacterial filtrates (antivirus) to which they showed a positive skin test 843 per cent improved whereas only 484 per cent of the patients treated with autogenous streptococcus vaccine showed improvement.

Psoriasis as Possible Allergic Manifestation—To investigate the question of an antigenic factor in the scales of psoriasis lesions, Adamson collected scales with a minimal admixture of blood serum or other foreign substances. The lipoids were removed with two washings in ether and the dried scales were pulverized in a mortar. Three types of extracting fluid were used: physiologic solution of sodium chloride, buffered saline solution and alkaline saline solution. The latter yielded the most satisfactory extract. Five grams of the pulverized scales were placed in 100 cc of the extracting fluid and kept in the icebox for five days. The extract was then passed through a Seitz filter and proved by cultural method to be sterile. Chemical analysis revealed a nitrogen content of 0.395 mg per cubic centimeter. This product was slightly irritating to the normal skin, therefore dilutions 1:4 and 1:8 with respective normal contents of 0.1 and 0.05 mg per cubic centimeter were made. Intradermal injection of these two dilutions gave negative reactions in ten normal skins. Six cases of psoriasis were available and in each case positive reactions occurred at the sites of the intradermal injection of 0.02 cc. of the weaker dilution. Atopic reagents in the blood were not demonstrable by passive transfer, nor were precipitins demonstrable in vitro.

The Passage of Bacteria from Lungs to Blood Stream—Tuttle and Cannon introduced bacterial suspensions of Staphylococcus aureus, Bacillus prodigiosus and Streptococcus haemolyticus into the left lower lobe of the lungs in fourteen healthy dogs and took cultures of samples of blood from the femoral artery and lymph from the thoracic duct at frequent intervals during the first sixty minutes. In the animals injected with staphylococci and prodigiosus bacilli both the blood and the lymph remained sterile throughout the period of observation. The bacteria were demonstrable in the lungs at the end of the experiment, many already engulfed by septal cells. In the dogs injected with hemolytic streptococci the micro-organisms quickly entered the blood stream, whereas the thoracic lymph remained sterile in most instances, proving that the bacterial passage from the lungs into the blood stream was direct, rather than indirect by way of the lymphatic channels. It is probable that the differences in response of the pulmonary tissues to the micro-organisms employed depend to a large extent on the varying degrees of injury to the cellular and tissue barriers within the lungs and that the experimental bacteremia occurred because of increased permeability of these membranes induced by the virulence and toxicogenicity of the bacteria.

Preservation of Purified Suspensions of Virus of Vaccinia—Behrens and Ferguson tested the stability of a virus free of protective organic cellular matter and observed the effect of various substances when stored under like conditions. The viruses that they employed were dermavirus, obtained from commercial calf pulp and neurovirus, obtained from the

original Levaditi strain, which was cultivated in vivo in rabbits. Suspensions of these viruses were made up with physiologic solution of sodium chloride and purified by the iso-electric point method and by the use of Brewer-Kraybill aluminum gel. They found that of the preservatives tested gelatin and peptone gave the best protection to the virus, when used in percentages of 0.1 and 1, respectively.

Surgery for Cancer of Breast—From 1919 to and including 1928 Coventry and Moe operated on ninety-one patients with carcinoma of the breast. Twenty-four are living and well. Two are living with recurrence. Sixty-one are dead and four are untraced, thus making 26.3 per cent of so called five-year cures. The average duration of symptoms in the entire group was 11.2 months from the time the symptoms were first noticed until the operation was performed, while in the groups of five-year cures the average duration of symptoms was only four months and in the seven and ten year groups it was still less. This observation impresses the fact that early diagnosis and early treatment are of primary importance. Of the twenty-four patients living and well five years or more, twenty-one had radical operations and three had semiradical procedures. Mere amputation or excision of the tumor produced no five-year cures. Roentgen treatment was given to eleven of the twenty-four patients, while no radiation was given to thirteen. The duration of symptoms, size of growth and presence of metastasis played no apparent part in the end results, as approximately an equal number of early and late cases were found in the two groups. The authors firmly believe that the radical operation as advocated by Halsted and Meyer is the most effective weapon at hand in combating this disease. A lump in the breast demands biopsy. There is a need for a cooperative program between the surgeon and the radiologist to assure the administration of proper and effective dosage.

New Conception of Pellagra—Tucker believes that dietary deficiency, including that of vitamin G, probably contributes to the susceptibility to pellagra, and so in a lesser degree do chronic alcoholism, chronic tuberculosis, chronic digestive disturbance, prolonged mental states and morphinism. In his experience many patients have recovered without yeast, liver or much food supposed to be rich in vitamin G. Inquiry from six Southern state hospitals reveals that the superintendent of four reported the development of pellagra in patients on the so called pellagra preventive diet. In considering the possibility of a virus infection as the cause of pellagra he points out that pellagra resembles acute anterior poliomyelitis, smallpox, herpes zoster, influenza and the form of encephalitis that follows influenza in its epidemiology, place incidence, seasonal tendency and its acute, chronic and recurrent forms much more than it does scurvy, rickets, beriberi, malnutrition and other dietary deficiency diseases. But the pathology is the most important factor pointing to the possible cause of pellagra. In two brains, six cords and two sympathetic ganglionic chains examined by the author pellagra was found to affect the brains but slightly, the cords diffusely and especially in the cervical and lumbar enlargements, and the spinal sympathetic ganglionic chains extensively. He was led to the conjecture that a virus would be the most likely agent to cause this neuropathologic distribution. In support of the contention that the pathology of pellagra is chiefly neurologic, he calls attention to the literature of necropsies of the central nervous system. Reflex and other organic neurologic signs are found in probably 25 per cent of pellagra patients and mental symptoms are, of course, not infrequent. Organic neurologic signs and mental symptoms are common to practically all very severe cases. Involvement of the spinal cord will account for the organic neurologic signs, while a general toxemia with, at times, infiltration to the brain will account for the psychoses and involvement of the spinal ganglionic sympathetic chain with its spinal cord connections for the cutaneous and gastro-intestinal manifestations. A filtrable virus is the most likely cause of such distribution of involvement.

Relation Between Quinine Concentration and Malaria Parasite Count—Chopra and his associates performed experiments on monkeys to determine whether with the maximal concentration of quinine obtained in the blood the parasites exhibited any tendency to increase or decrease in number or to show degenerative changes. *Silenus rhesus* monkeys were infected with strains of *Plasmodium Knowlesi* from another infected monkey, and the erythrocyte and the corresponding parasite counts were determined. Quinine was then administered by the intramuscular or the intravenous route, and the concentration of the alkaloid in the blood and parasite counts were determined at intervals. There was no direct relationship between the concentration of quinine in the blood and the parasite count at any particular time. The highest concentration of the alkaloid attainable without producing too severe toxic effects produces no apparent reduction in the number of parasites or degenerative changes in them. On the other hand in the majority of cases there was a definite apparent increase in the number of parasites per cubic millimeter of blood after the administration of quinine. The action of quinine on the parasites does not appear to be direct but is probably synergistic to other mechanisms set up in the body. It has been observed that once the number of parasites approximates one million per cubic millimeter no amount of quinine, however administered, is of any avail.

Renal Sympathectomy and Renal Sympatheticotomus—Harris issues a warning against the promiscuous application of renal sympathectomy. He has limited its field of application and has in no case employed it in conjunction with nephropexy or decapsulation. It has been carried out solely for relief of the pain of increased intrarenal tension in cases of urinary stasis arising from neuromuscular dysfunction of the renal pelvis, calices and upper portion of the ureter—a definite type of obstructive nephropathy (renal sympatheticotomus). Renal sympathectomy may be employed in cases of this type with a certainty of success that is exceeded by few other operations. Of the etiologic factors concerned, little or nothing definite is known. The disease rarely attacks people in robust health. Worry and overwork have been features in nearly all cases. The attacks of pain are believed to be brought about by increased excitability of the sympathetic nerve supply to the kidney, though this sympathetic overactivity, while commonly unilateral, may often be shown to be much more comprehensive in its distribution. Evidence of this is to be found in muscular hypertonus, illustrated by increased excitability of the knee jerk on the affected as compared with the normal side, with delayed relaxation time and absence of the normal oscillations. Hypertonus, as estimated by the knee jerk, is liable to variation from time to time in the same patient and is subject at the time of examination to the phenomenon of fatigue. Attention should be focused on the first tests made and the patient should be properly prepared. It is reasonable to suppose that this periodic variation of hypertonicity also applies to the kidney, affecting the entire musculature. The intermittent nature of the pain would thus find a ready explanation. The renal stasis as exemplified by the delayed emptying time of the renal pelvis after pyelography is constantly found. The three stages of renal sympatheticotomus are irritability or overexertion, exhaustion and dilatation or paralysis. In the first stage systole predominates, in the second diastole, and in the third hydronephrosis is present. Immediate and permanent relief of symptoms is afforded by renal sympathectomy in stages one and two. In stage three the aid of plastic surgery may be necessary to overcome secondary organic obstruction. The author believes that the best interests of surgery in general and of renal sympathectomy in particular will be conserved by rigidly confining the operation of renal sympathectomy to the type of case described.

Use of a Derivative of Physostigmine in Treatment of Myasthenia Gravis—Pritchard confirms the clinical effects of dimethyl carbamic ester of hydroxy phenyl-tri-methyl ammonium methyl sulphite in the treatment of myasthenia gravis obtained by Walker. Of the seven cases described, all have shown a striking and immediate relief of symptoms to a degree not observed with any other remedy. Each of the seven patients has been examined before and after the injection into the buttock of the physostigmine derivative and atropine. The atropine is given to counteract the effect of the physostigmine derivative in causing slowing of the heart and peristalsis of the intestine. In each a measure of the maximal power of voluntary flexion of the fingers before and after has been obtained by means of a recording dynamometer. The effect of the injections has passed off almost completely in eight hours. A further injection resulted in recovery as before. A control injection with sodium chloride, after previous injection of the derivative of physostigmine—so that the patient was expecting a good result—gave only slight improvement in the hand grasps and no other symptomatic improvement. In the three patients in whom myographic registration has been possible, this clinical remission of symptoms has coincided with a change in the curve of tension developed under electrical stimulation from the form characteristic of myasthenia gravis to the normal form.

Surgery of the Lung Root—O'Shaughnessy outlines the following lesser known interventions on the lung root that he believes will have an increasing importance in radical or palliative treatment exposure of the lung root, operation on the bronchus, operation on the pulmonary artery and veins and surgery of the nerves of the lung root. It is believed that most of these interventions have a purely theoretical basis—that none of them have been performed often enough to enable a true judgment—and that the surgery of the lung root has no real practical basis. On the other hand, four years ago it was the common opinion that total extirpation of the lung was a purely experimental procedure many animals had survived but no men, and the operation was never attempted. Since 1931 when Nissen demonstrated that extirpation was a practical proposition, the operation has been attempted more often. In a recent paper Archibald states that he has records of twenty-three cases with sixteen successes, and these figures do not include Mason's two successful English cases. This record seems to justify the pursuit of the less radical surgery of the lung root in the hope that some help may be given to that large group of sufferers from chronic disease of the lung for whom conservative therapy fails to provide even symptomatic relief.

Sugar Tolerance Curves in Diphtheria—In 124 cases of severe diphtheria graded according to Bies classification of extent of membrane, Begg estimated the sugar tolerance curves at various stages of the disease all the patients received intravenous and intramuscular antitoxin and dextrose intravenously and orally and half of them received, in addition, insulin in doses depending on the sugar tolerance tests. To avoid bias in selection, alternate cases within the same age periods and clinically of the same degree of severity were placed in the insulin and control groups respectively. As far as the author's data are concerned, the efficacy of insulin in the treatment of diphtheria cannot be demonstrated. The response of the body to intravenous dextrose is constantly abnormal and results in higher blood sugar tests. The degree of variation is a sensitive index of the severity of the attack and serves as a reliable guide to the progress of the disease. A fairly close association appears to exist between abnormalities in tolerance curves and involvements of the cardiovascular mechanism. How much the former depend on the latter it is impossible to say. Insulin does not appear to change the character of the abnormal curves or to influence the course of the disease, as judged by the fatality and complication rates.

 *Autohemotherapy in Treatment of Bronchial Asthma K Maddox and R Back—p 277

Autohemotherapy in Treatment of Bronchial Asthma—Maddox and Back employed autohemotherapy in the treatment of bronchial asthma in twenty-four children less than 16 years of age seventeen adults all of whom except two

were less than 40 years of age, and two typical examples of vasomotor rhinitis. After a thorough examination, 10 cc. of blood was taken from the median basilic vein and injected forth with into the buttock without admixture of citrate or any attempt to separate the blood elements. This was repeated five times at intervals of a week. The patient then entered on a period of observation varying from three to twelve months. Any beneficial results obtained were directly proportional to the youth of the patient, and therefore to the less complicated character of the asthma. The purer the allergy, the better were the results obtained from the injections. Young asthmatic patients constituted by far the greater part of those patients showing improvement, and in approximately three fourths of the children the frequency of the attacks was appreciably reduced while in every instance some alleviation in severity was manifest. Hemotherapy was more successful in children of the first decade than in those of the second. The presence of skin sensitivity to the scratch method presaged a better result from autohemotherapy the average age of onset of asthma in this series was no earlier in children with a family history of the disease.

 Surgical Unit in a Sanatorium J B McDougall and A D Bardswell—p 267

Bactericidal Power of Blood Serum in Tuberculosis—Pagel draws the following conclusions from his investigations on the bactericidal power of the blood serum in seventy cases of pulmonary tuberculosis. 1 There are a certain number with a definite power of the blood serum to prevent or diminish the growth of tubercle bacilli. This result agrees with that of the fundamental experiments of Courmont and Gardère. 2 On the other hand, the statement of Kirchner is confirmed that glycerin broth as such, is not a suitable culture medium but is rendered a good medium by the addition of normal serum. This is the basis of a simple technic for proving the preventive power of certain serums of tuberculous patients in a regular and uniform manner. 3 In spite of the fact that the majority of the author's cases with a high bactericidal power of the serum showed healing processes, it does not seem to him that the preventive power of the serum is due to the clinical state and extent of a tuberculosis but to its peculiar type of development. Such cases are not confined to tuberculosis of the skin (in which form Kallós and Nathan have proved the bactericidal power in an instructive manner) but belong to the universal complex of the chronic hematogenic tuberculosis of the lung. 4 The frequent occurrence of early pulmonary infiltrations in this group with a high bactericidal power of the blood serum may be a hint as to the hematogenic origin of such infiltrations. Whether the bactericidal power of the blood serum in cases of this type is connected with the content of antibodies, beta tuberculin (Kallós) or tryptophan in the blood serum as indicated in cases of tuberculosis of the skin by Kallós and Nathan, has to be proved by further investigations.

Erythrocyte Sedimentation in Myocardial Infarction—Bickel and his collaborators studied the rate of blood sedimentation in patients following coronary thrombosis. The Westergren method was used. Parallel observations of fever and leukocytosis were made. The fever and leukocytosis occurred early after the infarction but returned rapidly to normal. A markedly increased rapidity of erythrocyte sedimentation did not develop for about two or three days after the infarction reached its maximum in a day or two and returned to normal after several weeks. In this respect there was a difference with the febrile and leukocytic responses. The reason for an increased rate of blood sedimentation—which occurs usually only in infectious states and malignant tumors—is not clear. It is probably connected with disturbances in fibrinogen. The authors believe that the use of the erythrocyte sedimentation test in myocardial infarction will prove a useful adjunct to the clinical signs and the electrocardiogram in deciding how soon after myocardial thrombosis a patient may return to some activity.

*Hypochloremia and Vomiting R S Mach —p 342

Hypochloremia and Vomiting—Mach reports two cases in which a true dechloridation resulted from hypochloremia secondary to persistent vomiting. Careful observation allowed him to conclude that a plasma and erythrocyte hypochloremia may be observed in the course of repeated vomiting of patients with achlorhydria. This is accompanied by uremia and an increase in the alkali reserve. The hypochloremia of achlorhydric patients may be explained by the continuous loss of gastric fluid containing chlorides even in the absence of hydrochloric acid. The uremia of the hypochloremic patients is a uremia without renal damage, as was shown by the proved anatomic integrity of the kidneys at necropsy in his two cases.

*Cerebral Disturbances in Course of Acute Articular Rheumatism G Gottsegen —p 280
Action of Some Metallic Ions on Tonicity of Myocardium A Moukhtar —p 281

Coagulation of Blood and Blood Platelets—Lenggenhager points out that the rapid coagulation of the blood outside the body is generally ascribed primarily to the blood platelets, which, stimulated by the foreign surface and by the air, produce a substance (thrombokinas or cytozym) which, together with calcium and the blood substances prothrombin or serozym produces thrombin. To determine whether or not the kinase is derived chiefly from the blood platelets, the author made experiments which demonstrated that, as formers of thrombokinas, the blood platelets have practically no significance and thus are not responsible for the coagulation of blood outside the body. The coagulation is induced by the transformation of a prokinase that circulates in the blood and which, under the influence of evaporation and of the adhesiveness of the surroundings and in the presence of calcium ions, produces the thrombokinas which in turn, together with the prothrombin of the blood and in the presence of calcium ions, produces thrombin, the coagulation ferment. This explains also why normal coagulation time exists in thrombopenia.

Cerebral Disturbances in Acute Articular Rheumatism—Gottsegen describes two cases of articular rheumatism in which a severe cerebrospinal symptomatology (restlessness,

stupor, delirium, reflex disturbances, rigidity of the neck) developed during the second week. These symptoms disappeared again after a few days, and a short time later the articular symptoms disappeared likewise. The author considers this disorder a milder form of the meningo-encephalitis rheumatica recently described by American authors.

*Research on Secretion of Bile in Drainage of Biliary Tract E Zilocchi —p 301
Experimental Research on Pulmonary Prolapse O Betto —p 361
Contribution to Study of Torsion of Great Omentum E Lucina —p 388

Hepatic Function in Relation to Anesthesia—Teneff studied the hepatic function of patients having diseases involving the liver and of those with diseases of the biliary tract before and after operation. He also studied the influence of the surgical drainage of bile on the hepatic insufficiency of patients having biliary calculi and hepatogenous icterus. He investigated the glycemia on a fasting stomach and the glyceimic curve after oral administration of 40 Gm of dextrose, the amino-acidemia on a fasting stomach, the amino-acidemic curve and the amino-aciduria after oral administration of 50 Gm of gelatin the bilirubinemia, the retention of bengal red and the daily elimination of urobilin. In all patients having diseases of the biliary tract, the functional tests indicate a degree of hepatic insufficiency that is aggravated by anesthesia and by operation. The postoperative aggravation depends not only on anesthesia but also on surgical intervention, because the two factors act at the same time and perhaps with the same intensity on the liver. Drainage of the biliary tract acts favorably on the functional condition of the liver only when the insufficiency is due principally to biliary stasis and to icterus. Liver function is improved in the case of stone in the common bile duct and in cases of hepatogenous icterus, while it has not had any benefit in the case of stone of long duration without stasis and icterus. Thus it is not possible to judge function conditions of the liver and to formulate a prognosis from results obtained by a single method. Several methods should be employed in all cases.

Secretion of Bile in Drainage of Biliary Tract—Zilocchi studied the bile secretion of seven patients operated on for drainage of the biliary tract, three for partial and four for total drainage. He found that immediately after operation there is a secretion of dark bile which lasts from five to six days gradually returning to a normal color. During the transition from dark to light bile the changes in the daily secretions become accentuated. These changes are slight in cases of total drainage but are marked in those of partial drainage. In total drainage the nocturnal bile is more concentrated than the daily bile, whereas in partial drainage the bile is secreted during the night while during the day there is a flow of clear fluid resembling cystic secretion. The quantity of bile secreted during the first day was constantly less than that of the following days, which is attributed to the action of the anesthetic on the liver. Research on the amount of mucus in the bile gave constant results. In bile removed during or after intervention by means of puncture of the gallbladder, the amount of mucus showed an increase of from 2 to 4 per cent. The degree of change in the biliary pigments corresponds to the change in the color of the bile. Immediately after operation the pigments are present in large quantities. By the second day there is a rapid diminution of the pigments, although a large amount is still present for from five to six days, which then gradually reaches a minimum value. The notable increase in pigments in the immediate postoperative period is due to (1) the reabsorption of extravasated blood and the hemolysis produced by the anesthetic, (2) the anesthetic itself, which diminishes the secretion of water, causing a relative increase of the concentration, and lowers the threshold of elimination for the pigments of the hepatic cells, (3) the elimination of pigments from the organism in cases in which icterus exists, (4) the relative dehydration in the immediate postoperative period, and

(5) the functional state of the liver. As to the elimination of cholesterol, two patients showed an increase in the bile one a diminution and two the normal quantity. The author believes that food and fasting do not influence the elimination of cholesterol, because in postoperative fasting of several days' duration there was no decrease in elimination. Cholesterol is not derived solely from alimentation but may be formed in the organism independently of it. The hepatic cell is only the medium of elimination.

Trypanosomiasis in Man Case O. A. Fitte—p 432
Mechanism of Phrenicectomy A. P. Heudtlass and O. Garre—p 433

Respiratory Tests in Pulmonary Tuberculosis—Raimondi and Scartascini say that the respiratory tests in pulmonary tuberculosis show marked changes, especially related to the vital capacity and to the respiratory indexes. Immediately after pneumothoracic insufflations the pulmonary ventilation diminishes. The respiratory indexes of patients with pulmonary tuberculosis improve as a result of the improvement of the pulmonary processes due to artificial pneumothorax. Both the evolution and the retrogression of pulmonary tuberculosis are in direct relation to the respiratory tests. The respiration of a 5 per cent mixture of carbon dioxide in oxygen causes a greater amplitude of respiration and increases the frequency of respiration and the time of voluntary apnea.

Repair of Ventral Hernia by Means of Transplanted Fascial Strips J. G. Knoflach and H. von Brucke—p 41

*Incidence of Embolism and Thrombosis in Surgical Clinic of Innsbruck and First Surgical Clinic of Vienna P. Huber—p 47
Spontaneous Renal Fistulas P. Deuticke—p 69

Study of Anesthetics—The object of this study, according to Starlinger and Kiener, was to establish the safety of various methods of anesthesia. The material surveyed consisted of major surgical operations performed from 1929 to 1934 in the First Surgical Clinic of Vienna. There were altogether 7,926 major operations and twenty-two fatalities which took place in the course of the operation or immediately after. The number of operations performed under ether anesthesia was 3,646, under local anesthesia, 3,244, under nitrous oxide gas anesthesia, 863, under tribrom-ethanol, 131, and under evipan 42. A careful analysis of the twenty-two fatalities revealed that in only one instance was the death caused primarily by the anesthetic, the method being that of spinal anesthesia. A statistical comparison of the postoperative morbidity and mortality as seen especially in the surgery of the upper part of the abdomen confirmed the fact that nitrogen monoxide gas anesthesia in combination with local anesthesia or with addition of small amounts of ether is the least harmful. The number of ether anesthetics given in the clinic showed a decline, while that of nitrogen monoxide combination anesthesia showed a rise. Tribrom-ethanol, evipan and spinal anesthesia are assigned an entirely insignificant part as anesthetics.

Embolism and Thrombosis—According to Huber the incidence of postoperative thrombosis in the Vienna clinic was relatively twice as frequent as in that of the Innsbruck clinic. The difference is in part accounted for by the nature of the surgical material and in part by the greater tendency to thrombosis on the part of the Vienna population. The incidence of thrombosis in Vienna showed a considerable rise above the prewar and war periods. The author cannot confirm the statement of Hutter and Urban that thyrotoxic patients and jaundiced patients are not subject to this complication. Age is no protection against thrombosis. He reports an incidence of 0.36 per cent in the first decade. These thromboses however occurred only in severe septic conditions. The importance of infection in the etiology of thrombosis diminishes with increase

in age. The most frequent localization of the thrombi was in the lower extremities. These, as a rule, were distant thrombi, occurring 202 times as compared with thirty-eight instances of thrombi localized in the operative field. Thrombosis of the pelvic veins gave rise to local and distant thrombi in about equal proportion. The author points to great frequency of thrombosis of the portal vein and of the jugular vein. The latter occurred as a complication of suppurative processes of the face and neck. In a total of 324 postoperative thromboses there were ninety-seven instances of thrombosis localized in the operative field and 227 instances of distant thrombosis. The occurrence of spontaneous venous thrombosis was rare and was either due to unusual overexertion or arose without surgical intervention in the course of some diseases that give rise to postoperative thrombosis, such as carcinoma of the breast, peritonitis or suppuration. The incidence of fatal pulmonary embolism in the Vienna clinic was even greater than the tendency to thrombosis when compared with that of Innsbruck. The indication for surgical intervention in the case of embolism of the pulmonary artery is made difficult by the uncertainty of the diagnosis of the condition. Of the seventy-five fatal postoperative pulmonary artery embolisms in the Vienna material, clinical diagnosis was made in fifty-two. Eight of the fatal embolisms occurred on the day of operation, five one day later and three on the second, another three on the third and six on the fourth postoperative day. The Trendelenburg operation was instituted in one case for an erroneous diagnosis of pulmonary artery embolism. In six correctly diagnosed cases the operation failed to bring about even a temporary improvement. The author reports ten cases of paradoxical embolism, a crossed embolism due to the existence between the two auricles of a patent foramen ovale. There were seventy-six instances of arterial thrombosis. Because of the poor results obtained with surgical intervention, the author recommends that arteriotomy should give way to conservative treatment with spasmolytic means.

*Pulmonary Hemorrhage in Tuberculosis and Hemorrhagic Diathesis J. Leltner—p 100

Meinicke's Seroreaction for Tuberculosis—Böhm and Gruner assert that the Meinicke reaction for tuberculosis is a reaction of high sensitivity and specificity. They refer to an earlier publication for the description of the technic and discuss the observations on 500 patients, in some of whom the test was repeated several times. They reach the conclusion that Meinicke's reaction compares favorably with the Besredka reaction. They think that a clearly positive reaction, in which nonspecific interference can be excluded, makes a tuberculous etiology of the existing disorder highly probable.

Phytotoxic Index in Pulmonary Tuberculosis—García and García-Miñón studied the phytotoxic index of 100 patients with pulmonary tuberculosis. They made in all about 220 tests, white lupine (*Lupinus albus*) serving as the test object. He summarizes his observations as follows: 1 The phytotoxic index has no diagnostic value in pulmonary tuberculosis. 2 Together with other clinical data (roentgenologic and laboratory examinations), the phytotoxic index has prognostic value in pulmonary tuberculosis. 3 In the benign cases, the phytotoxic index fluctuates between 42 and 76; that is, it is reduced (normal 76). In evolutive fibrocaseous cases, the phytotoxic index is increased to values fluctuating between 80 and 100. These values are surpassed during the preagonal period. 4 In patients with chronic nonevolutive processes the phytotoxic index fluctuates between 40 and 76 in the acute forms the index increases to values between 76 and 85. During periods of exacerbation with tuberculous cachexia, the phytotoxic index

increases to values from 86 to 92 and during the last stage it increases to from 93 to 129. This proves that the phytotoxic index is directly proportionate to the severity of the tuberculous disorder. 5 All patients in whom the phytotoxic index exceeds 100 either die or are in a grave condition. 6 During the advanced stage of tuberculosis the serum contains substances that greatly stimulate the growth of lupine roots. The nature of these substances is as yet unknown. 7 If concentrated tuberculin is added to the nutritive salt solution in which the lupines are kept, the growth is inhibited in proportion to the concentration of the tuberculin. 8 Repeated tests with the same blood revealed analogous results. 9 The term "phytotoxic index" is not entirely correct and should be replaced by one that expresses not only the toxic but also the stimulating effects. The authors suggest the term "phytopoietic index."

Tuberculosis and Hemorrhagic Diathesis—Leitner asserts that tuberculosis is frequently the etiologic factor of forms of purpura, which occur in tuberculous patients. Purpura is most frequent in severe septic forms of tuberculosis or during the cachectic terminal stages. In these cases it is the manifestation of a terminal impairment of the hematopoietic organs and of the reticulo-endothelial system. In the milder forms of tuberculosis, purpura is not so frequent; it occurs, nevertheless, and generally becomes manifest during a new exacerbation and later subsides again. The author classifies this form with the anaphylactoid group of purpura and maintains that it is elicited by the tuberculous intoxication. Purpura is quite frequent during tuberculosis of the spleen. This observation is significant because an early diagnosis makes a correct treatment possible. The purpura has been known to disappear following extirpation of the tuberculous spleen. The author investigated whether tuberculosis may produce a hemorrhagic diathesis that does not become manifest as a purpura but only as a predisposition to pulmonary hemorrhages. He thinks that the contradictory reports in the literature are partly due to the fact that only one symptom was investigated. It is known, however, that a predisposition to hemorrhage may develop when some factors change while others are unaltered. The author studied all pertinent factors: coagulation time, bleeding time, number of thrombocytes, retraction of the blood clot and the vascular factor. Studies on thirty-six patients disclosed that a latent tendency to hemorrhage in the form of an atypical hemorrhagic diathesis is the cause of pulmonary hemorrhages in only a small percentage of tuberculous patients. Moreover, it cannot be answered definitely in all cases whether this tendency to hemorrhages was caused by the tuberculosis or existed previously. Nevertheless, it seems that in a small number of cases pulmonary hemorrhages develop on the basis of a hemorrhagic diathesis, since tests on tuberculous patients without hemoptysis hardly ever reveal a tendency to hemorrhage.

Quinine Intoxication and Quinine Idiosyncrasy—A. Hauer—p. 332
Blood Pressure Reducing Hormones as Cause of Protein Shock—G. de Nito—p. 339

Quinine Intoxication and Quinine Idiosyncrasy—Hauer shows that the prolonged use of quinine by inhabitants of the temperate zone living in the tropics produces an increasing sensitivity to quinine and eventually the acquired form of idiosyncrasy. He describes a case of acquired hypersensitivity to quinine. The great changes that became manifest in the blood picture as the result of the shocklike attacks elicited by quinine demonstrate the danger of the attacks. The nature of quinine idiosyncrasy is still problematic, but the attacks of fever elicited by the quinine give it the appearance of an acute intoxication. The author warns the practitioner against a too liberal use of quinine and stresses that the examination of an inhabitant of the temperate zone for his fitness for life in the tropics should not omit the test for idiosyncrasy to quinine.

Hormones as Cause of Protein Shock—De Nito states that among the blood pressure reducing substances the hor-

more formed principally in the lymph nodes, and therefore designated "lymphoganglin," is the most important. Blood pressure reducing principles are found also in plants, and the latter substances closely resemble the animal hormone. Examination of the biologic action of the blood pressure reducing hormone disclosed a close resemblance to the modifications produced by protein shock, namely, reduction in blood pressure, leukopenia followed by leukocytosis, mononucleosis, change in the temperature, acidosis, reduction of the alkali reserve of the blood, changed coagulation time, reduction in the viscosity and in the refractometric index of the blood serum (hypoproteinemia) and hyperglycemia with secondary hypoglycemia. This similarity in the reactions raises the question of the presence of proteins in the hormone, but on the basis of a thorough chemical analysis of the hormone the presence of protein bodies could be excluded. He thinks that the protein substances first act on the lymphatic system and cause it to excrete a large amount of blood pressure reducing hormone into the circulation. The hormone in turn acts on the sympathetic nervous system, and thus the protein shock is produced. In discussing the therapeutic significance of the blood pressure reducing hormone, the author points out that it might be tried in cases in which the protein body therapy does not produce the desired results.

Fatal Intoxication Caused by Seeds of Castor Oil Plant—Abdukkadir Lutfi—p. 416
Cutaneous Lesions Caused by Reducing Remedies Containing Boric Acid—A. M. Memmesheimer—p. 418

Calculation of Basal Metabolism from Pulse Frequency and Pulse Pressure—Wiechmann shows that, of the formulas suggested for the calculation of the basal metabolism, the modified formula of Read gives the most reliable results. In patients with cardiac and vascular disturbances, however, the formula cannot be used. The results obtained by Read's formula and those determined with the gas analytic method often show a surprising conformity. This applies also to the thyrotoxicoses. However, in borderline cases and in mild forms of thyrotoxicosis the formula is not entirely reliable. The analysis of the gas exchange is not made superfluous by Read's formula. The calculation according to Read only complements the use of the apparatus for gas analysis. Read's formula is especially valuable in estimating the effect of therapeutic measures. The author thinks that in the beginning it is advisable to use the apparatus for gas analysis and Read's formula side by side, but later the calculation according to Read's formula alone is sufficient. It is desirable that the determination of the pulse frequency and of the blood pressure be done by the same examiner.

Reducing Remedies Containing Boric Acid as Cause of Skin Disorders—Memmesheimer states that a woman, aged 49, consulted him on account of an itching reddishness of the face, which later spread to the head, the neck and the trunk. The skin became thickened and showed fine scales and blisters. Questioning disclosed that she took a reducing powder. A cutaneous test with this powder gave a positive reaction. After the woman discontinued taking the powder, the skin disorder disappeared rapidly under the influence of the usual local therapy. Subsequently the author observed two other cases presenting a cutaneous disorder that resembled pityriasis rosea. Here again cutaneous tests the appearance of the disturbance soon after the women had begun taking a reducing preparation and the rapid disappearance of the skin disorder after the use of the reducing preparation was discontinued indicated that the cutaneous lesions were due to boric acid. A fourth patient, a druggist, suggested of her own accord the possibility of a connection between her strongly itching exanthem and the taking of a reducing preparation. Here too the suspected connection could be demonstrated. The author concludes that in cutaneous disorders of stout persons the possibility of such an origin should be taken into consideration.

- *Immediate and Late Results of Lumbar Sympathectomy in Spontaneous Gangrene A Filatov—p 491
- Evaluation of Immediate and Late Results of Operative Treatment of Syringomyelia A Juzelevsky—p 503
- Toxic Effect of Putrid Pus in Pleural Empyema E Schneider—p 521

Intramural Nerve Plexuses in Diseases of Stomach—Rieder reports a histologic study of the nervous apparatus of the stomach in ninety-four cases. Of these, seventy-one were cases of gastric or duodenal ulceration and nine were complicated by a perforation. There were six cases of gastritis, five cases of gastric cancer and three specimens resected because of a suspicion of ulcer but in which neither gastritis nor ulcer was found. To demonstrate the nervous structures the author used a modification of the Bielschowsky-Gros method. More or less severe alterations of the intramural nerve ganglions were found scattered over the whole resected specimen in every case. Here and there were found round cell accumulations between the nerve fibers. The same alterations were found in the three cases in which gastric resection was performed because of the existence of symptoms of three years' standing but in which neither gastritis nor ulcer was found. Alongside the degenerative processes were found regenerative processes as well particularly in the crater of the ulcer and its vicinity. The author does not feel justified in considering the pathologic alterations in the three specimens that did not exhibit either gastritis or ulcer as forerunners of these lesions.

Lumbar Sympathectomy in Spontaneous Gangrene—Filatov reports the results of lumbar sympathectomy in thirty-four cases of spontaneous gangrene. The immediate effect was excellent in seventeen, satisfactory in eleven and negative in five. One patient died shortly after the operation from wound infection and general sepsis. Of fourteen cases that were followed for from one to six years a permanent result was obtained in nine and a satisfactory result in two. In the remaining three cases morbid manifestations returned six months, two years and three years after the operation. The author collected 294 cases from the literature which, together with the author's new thirty-four cases and the fifty-one reported by his chief Hesse in 1929, total 379 lumbar sympathectomies performed for spontaneous gangrene. The immediate result was good in 80 per cent of these, and in many the results remained permanent. He concludes that lumbar sympathectomy is a well founded procedure in cases of spontaneous gangrene. However, a satisfactory result can be expected only with the application of a faultless technic insuring a fairly complete desympathization of the extremity. Success likewise depends on a rigorous selection of cases. Sympathectomy can be expected to bring about an improvement only in cases presenting vasomotor disturbances and in the absence of extensive thrombosis. The author considers the protein test the most reliable indication for the operation. In the evaluation of the test one should consider not only the rise of the skin temperature of the extremity but likewise the changes in the pulsation of the peripheral vessels and the subjective sensations of the patient.

- *Studies on Regional Differences in Intracutaneous Tests W Schmidt—p 378
- Therapy Resistant Syphilis Particularly Parenchymatous Keratitis and Its Treatment with Quinine J Schereschewsky—p 381

Significance of Hypophysis for Disease of Kidney—Marx points out that clinical and experimental observations have given rise to the question whether the hypophysis plays a part also in the disorders of the kidney. The answer has become more difficult since recent studies on the hypophyseal system and its functions have uncovered more new problems than definite results. The interrelation between nervous and hormone processes, the connections between the anterior and posterior

lobes and the question of the homogeneity of the different hormones are being disputed. Moreover, the conceptions about certain renal diseases have changed. Nevertheless there is one form of renal disorder in which an involvement of the hypophyseal system is generally conceded, namely, the renal disorders of the toxicoses of pregnancy, for the blood of patients with these disorders was found to contain substances that increased the blood pressure and inhibited the diuresis. Similar substances have been found also in patients with so-called pale hypertension. To determine whether these substances are a hormone of the posterior lobe of the hypophysis, the author tested their effect on the diuresis. He found that the substances extracted from the blood of patients with renal disease, with hypertension or with epilepsy not only increase the blood pressure but also inhibit the diuresis and effect a considerable increase in the sodium chloride concentration of the urine. This made it probable that these were the same substances that Anselmino and Hoffmann had detected in the blood of women with eclampsia. The author mentions other disorders in which changes in the hypophysis concur with renal disturbances: diabetes insipidus and tumors of the hypophysis. Moreover, a number of hypophyseal changes have been observed in patients with hypertension. After describing animal experiments, the author formulates his theory about the part played by the hypophyseodiencephalic system in renal diseases in the following manner: The toxins that circulate in the organism during infectious diseases and produce changes in the water and the sodium chloride content of the plasma of patients with renal disease cause an irritation of the hypophyseal system. This irritation becomes manifest in an increased production of the hormone of the posterior lobe of the hypophysis. This hormone is first secreted in the cerebrospinal fluid, from which it reaches the blood and, together with other factors (among them increased water intake), exerts its deleterious effect by producing hypertension of the vessels and hematuria and anuria in the kidneys. The author admits, however, that the changes in the central regulation represent only one factor among several that are responsible for the development of renal diseases. He does not deny that the direct action of the toxins of infection, of intestinal toxins and of waste products on the vascular system and the kidneys plays a part. In the treatment, the hypophyseodiencephalic as well as the other factors should be given consideration.

Regional Differences in Intracutaneous Tests—Schmidt states that in former experiments he tested the skin of various regions of the body for its sensitivity toward intracutaneous allergen injections and was able to determine that the skin of the back reacts much more strongly than that of the upper extremities, that on the forearms the reactions were more pronounced than on the upper arms, and that the flexor surfaces were more sensitive than the extensor surfaces. On the basis of these observations he pointed out that, in comparing the size of wheals, it is not permissible to draw conclusions about the monovalence or the predominating specificity of the allergen that has produced the strongest reaction, unless all intracutaneous tests have been made on the same region of the body. The author concedes that this factor is given due consideration by most examiners, in that they make the wheals only on the back or on the upper arm. Since this practice has been found generally satisfactory, it would be unnecessary to search for regional differences in more limited areas, if such differences had not been actually observed. It was noted that wheals induced four fingerbreadths below the spine of the scapula were only half as large as those produced in the region of the spine of the scapula itself. If this should be generally true, it would be of great significance for intracutaneous tests. The author studied this problem. He demonstrated by means of intracutaneous injections that adjoining cutaneous regions on the extensor surface of the upper arm and on the back generally produce wheals of equal size. However, near the olecranon the wheals become somewhat larger and at the transition from back to neck the wheals become smaller than on the other portions of the back. Consequently it is advisable to avoid the elbow region and the region above the spine of the scapula in intracutaneous skin tests. Aside from these exceptions, the upper arms and the back can be used for intracutaneous tests without hesitancy.

- Abortive Treatment of Peritonitis E. Wodak—p 348

Short Wave Therapy of Articular Disturbances—Last states that, in treating articular inflammations with short wave therapy, he always chose a dosage that the patient felt as a pleasant sensation of heat. In chronic cases, however, a dosage was used that would heat the joints thoroughly. The author never observed burns or other impairments that could be ascribed to excessive dosage. He employed a tube apparatus that could be set for any wavelength between 4 and 15 meters and also a spark gap apparatus that produced wavelengths of about 7 meters. He refrains from a definite evaluation of the two types of apparatus but emphasizes that only those types should be used which, while producing short wavelengths, permit the use of great energy in order to produce the necessary depth action within the joint. He concludes that short wave therapy is a valuable addition to the therapeutic armamentarium of articular disorders but admits that, like other treatments, it fails occasionally. The rapid disappearance of pains frequently permits the earlier application of a more active therapy. Repeated roentgenologic control examinations disclosed that existing anatomic changes in the joints were not influenced by short wave therapy. In florid tuberculous processes of the joints, short wave therapy is inadvisable.

Lemon Juice in Treatment of Diphtheria Carriers—Börngen found that lemon juice is an effective remedy against the diphtheria bacilli of carriers. Children were given three times daily two drops in the nose and twenty drops by mouth. This treatment was continued for ten days, and at the end of that period the diphtheria bacilli had completely disappeared. The author's observations were made in fifteen cases. He admits that the introduction of the lemon juice in the nose is somewhat painful but emphasizes that the efficacy of lemon juice surpasses that of the various dye solutions.

- Diuretic Action of Salts of Bile Acids B. Stanojević and Olga Andrić—p 416
- *Acute Appendicitis in Case of Tapeworm T. Altenkamp—p 418

Serodiagnosis of Gonorrhea—Poehlmann discusses the complement fixation reaction and points out that Meimcke has adapted his clarification reaction and Müller his conglobation reaction for the diagnosis of gonorrhea. He observed in comparative tests that the conglobation reaction of Müller is superior to Meimcke's clarification reaction and that the complement fixation reaction in turn is superior to Müller's conglobation. He says that the complement fixation reaction is valuable in the diagnosis and the differential diagnosis of gonorrhea particularly since a soluble gonococcus toxin has been employed as antigen. The complement fixation test is helpful in the deep gonorrheal complications in men and women, in which bacteriologic examination frequently fails, and particularly in the doubtful articular disturbances. In the latter conditions it is frequently the only method that permits a definite diagnosis. A negative outcome of the complement fixation test permits the exclusion of gonorrhea in these cases. However the complement fixation reaction is not absolutely reliable for the prognosis and for the determination of a definite cure of a gonorrheal process.

Action of Papaya Juice—Bodechtel and Kinkelin call attention to the juice of the fruit of the pawpaw tree (*Carica papaya*), which, because of its digestive action on proteins, has been designated as vegetable pepsin. The authors think that "vegetable trypsin" would be a more suitable term since it

decomposes protein bodies further than does pepsin and since it contains also a fat soluble component (lipase) and a rennin-like principle. Thus the papaya juice contains all the important digestive enzymes. However, since a dry preparation of this juice has a much weaker action than the fresh juice, attempts were made to combine it with a harmless but effective activator. This aim was realized by combination with another vegetable extract. The authors mention experiments by which it was demonstrated that this combination is harmless, well tolerated and an aid to digestion. They recommend this preparation in achylia, anacidity, dyspepsia and disorders of the bile passages.

Acute Appendicitis in Case of Tapeworm—Altenkamp states that he observed a number of cases of appendicitis in which oxyurids, trichocephali and ascarids were the cause, for they were found in the appendix and had produced the inflammation. Then he describes two cases in which segments of a tapeworm were found in the inflamed appendix. He emphasizes that, although in the reported cases the appendicitis could not be doubted, caution is necessary in deciding on laparotomy in cases of tapeworm, since appendicitis may only be simulated. He illustrates this with a case history. The operation is especially dangerous in the case of tapeworm, because the post-anesthetic vomiting may bring the larval form (*cysticercus*) into the stomach, and, after having lost their cystic membrane, they may commence their invasion of the organism. To be sure the simultaneous occurrence of tapeworm and *cysticercus* is rare (immunity?). The knowledge that a tapeworm is present should not be taken as an excuse for the postponement of a necessary operation. Even though it is known that a tapeworm is present, the decision regarding the necessity of an operation should be based on the same factors that determine the appendectomy in the absence of a tapeworm. The healing of the laparotomy wound should be followed by the expulsion of the tapeworm.

- *Observations on Fundus Oculi in Acute Polyarthritus A. Pillat—p 302
- Calculation of Date of Birth According to Naegle, L. Krael—p 305

Changes in Fundus Oculi in Polyarthritus—Pillat states that for a number of years he observed that patients who had an attack of severe acute articular rheumatism or chronic articular rheumatism quite often had choroiditic foci in the fundus oculi, which as a rule were far in the periphery so that they readily escaped observation. He examined the fundus oculi of twenty-eight patients and discovered seventeen who had choroiditis. In three other cases the choroid showed changes the nature of which could not be definitely identified, and they were not included in the number of choroiditis cases. Only eight patients were entirely free from changes in the fundus. He points out that, morphologically, the choroiditic changes observed in acute polyarthritus do not differ from tuberculous choroiditis. Moreover the patients had a high sensitivity to tuberculin and the Löwenstein blood culture for tubercle bacilli was positive in eleven of the seventeen patients. The author recommends ophthalmoscopic examination for patients with acute polyarthritus.

- Experimental Studies on Function of Reticulo-Endothelial System in Tuberculosis Z. von Bernáth—p 193

Respiratory Function in Pulmonary Tuberculosis—Risi found that tuberculous patients with artificial pneumothorax usually have a reduced vital capacity. In patients in whom ordinarily the reduction was slight, the pneumothorax

treatment often reduced the vital capacity more. The alveolar carbon dioxide tension during eupnea showed only slight differences. The respiratory dynamics showed supernormal and subnormal fluctuations, according to whether the disorder impaired the pulmonary ventilation in a greater or lesser degree. The duration of the voluntary apnea proved to be considerably reduced in nearly all cases, and the degree of the reduction ran parallel with the degree and extension of the disease process. The alveolar tension of the maximal voluntary apnea revealed no relation to the duration of the apnea. The differential alveolar median tension was nearly always below normal. The alveolar carbon dioxide exponent did not indicate a correlative ratio between the duration of apnea and the differential alveolar tension. This exponent showed such a conformity with the physical and physiologic condition of the respiratory apparatus that on the basis of its value it was possible to determine the severity of the existing changes relative to the restricted respiratory surface.

Granulosa Cell Tumors—Klaffen states that he has observed four more cases of granulosa cell tumors. The first case was that of a nullipara, aged 24. Formerly this patient had normal menstruation, but in the last four months she had become amenorrheal. After the extirpation of the granulosa cell tumor, menstruation set in again. The author gives case histories and points out in the conclusion that granulosa cell tumors may cause not only amenorrhea but also pathologic hemorrhages. In the cases here described the uterus was not removed and it was therefore impossible to determine definitely whether hyperplastic changes were present in the uterus. However certain symptoms indicate that such changes were present. After pointing out that the presence of granulosa cell tumor in children has been known to produce signs of early puberty, the author thinks that it cannot be doubted that granulosa cell tumors have a hormone action. He emphasizes, however, that a sex alternating effect of the hormone excreted by these tumors has not been proved as yet.

 Modes of Acute Cold Infections in Machine Factory Workers L S Girshberg—p 309

Dietetic Management of Pernicious Anemia—Sherman and his co-workers find that liver feeding alone without addition of meat, vegetables and fruit is capable of accomplishing a striking curative effect. Liver diet was effective in all forms of pernicious anemia but was not effective in hyperchromic anemias of other than the Biermer-Ehrlich type. The authors consider large doses of liver not necessary. They obtained satisfactory results with 150 Gm daily, and they consider 200 Gm the maximal daily dose. A powdered liver extract was effective only in recent cases. It had no effect in patients with two or more recurrences. The twenty-four hour urobilin content of the urine declined markedly on liver feeding. After from three to six months of persistent liver therapy, the urobilin of urine approached the normal. The twenty-four hour determination of the urobilin content of the urine serves as an accurate index of hemolysis and, therefore, of the condition of the patient. The study of feces shows a marked improvement under liver therapy in the utilization and digestion of substances making up Schmidt's diet. Neutral fat after three months of liver therapy is digested 100 per cent, while its absorption amounts to 57 per cent as compared with 8 per cent before the liver diet was

instituted. Digestion and absorption of muscle tissue increased after three months of liver therapy from 30 to 60 per cent. The authors have also noted an increase in blood sugar on liver diet and the presence of a normal hyperglycemic coefficient after a sugar test. With the application of uninterrupted liver diet an improvement was noted in the spinal cord symptoms.

Effect of Fifty Days' Fast—Gazenko and Slavin report their observations on the behavior of the gastro-intestinal tract in the course of fifty days of complete fasting. The subject was a normal man, aged 38, who expressed his intention of fasting fifty days because of a theoretical notion on his part that the fasting would rejuvenate his entire organism. The following observations were made. After the prolonged fasting the stomach exhibited atony with marked stasis and lowering of the secretory function. The intestine continued to form fecal masses apparently from its secretions and products of desquamation, which did not differ from ordinary feces on a light diet except in quantity. A certain small amount of vegetable material from previously ingested food remained in the fecal masses as late as the fiftieth day. This was explained by the atonic state of the intestine and the change in the bacterial flora. The fasting did not influence ascaris eggs present during the entire period of fasting. Excretion of urobilin was carried on almost entirely by the kidneys and amounted to from three to four times that of the normal quantity.

Influence of Natural Fats on Animal Structures—In his investigations on the influence of different components of cod liver oil on organic structures Agduhr found that the non-saponifiable fraction of cod liver oil is less injurious to mice than the saponifiable fraction as shown by the death rate and in certain cases by the organic lesions. The heart lesions, however, were as a rule more marked in the animals given the nonsaponifiable fraction. Especially extensive experiments were performed with vitamin D and with ergosterol and viosterol. Long-continued administration of ergosterol exerted a definite toxic influence on the organism of mice. Ultra-violet irradiation of ergosterol increased its toxicity especially on the liver, kidneys and adrenals. The lowered resistance of the mice against certain toxic substances, especially large quantities of ergosterol, on retardation of normal sexual functions is attributed to checking of the normal functions of the endocrine organs. The author says that pure vitamin D is considerably less toxic than viosterol when quantities with corresponding antirachitic effect are compared. Results point to gradual neutralization of the toxicity of the different constituents of cod liver oil.

TUBERCULOSIS AMONG EMPLOYEES OF THE MINNEAPOLIS SCHOOLS

FRANCIS E HARRINGTON MD

J ARTHUR MYERS MD

MINNEAPOLIS

AND

IDA LEVINE MD

DENVER

Throughout the nation school boards are contemplating the issuance of orders to the effect that all teachers and employees of school systems be adequately examined for tuberculosis. In a good many places such orders have already been issued and the work is in progress. Every physician is interested in the health of the children of this country even though he may practice a specialty remote from pediatrics. It is probable that during the next five years nearly every physician in this country will be called on to take a part in actual examination of teachers and children for tuberculosis or will be consulted by parents and others concerning the advisability of or information regarding such examinations. Health laws and regulations provide for examinations in several places, such as the following from one state:

Section 5384 Teachers, pupils etc. Certificate No teacher, pupil or employee about a school building who is afflicted with pulmonary tuberculosis shall remain in or about such building without having a certificate issued by the local board of health or by an agent duly authorized by said board stating that said person is in no sense a source of danger to others.

School Teachers pupils etc with Tuberculosis Section 2927 Causes for revocation or suspension (d) Affliction with active tuberculosis or some communicable disease shall be considered as cause for the suspension of certificate while the holder thereof is suffering from such disability.

As tuberculosis so frequently exists without producing any outward manifestations it becomes necessary for any individual to prove that the disease does not exist. Attorney General Peterson of Minnesota has ruled that "the skin test for teachers is reasonable exercise of the police powers of the school boards if required for the purpose of safeguarding the pupils of public schools." Attorney General Bricker of Ohio says "It is my opinion that it would be legal for either a board of education or a board of health to give the

tuberculin test to school children by means of the injection method or application of a salve, if it is found to be a reasonable measure for the protection of the public health and safety." Therefore it behooves every member of the medical profession to add to his armamentarium and the very latest methods of examination the most modern interpretations of his observations as well as the new procedures used in the treatment and prevention of this disease.

THE PROBLEM

That a tuberculosis problem exists in many school systems of the world cannot be doubted. In 1932 we called especial attention to this problem and cited some of the reports that had been made by such workers as Ickert Klein, Dietrich and Frost who had found that children taught by teachers with open tuberculosis showed a much higher incidence of positive tuberculin reactions than those taught by other teachers. Ickert found that as high as 93.5 per cent of the children taught by tuberculous teachers reacted positively, whereas only approximately 25 per cent of the pupils of teachers who did not have open tuberculosis had been contaminated. Klein observed that approximately 72 per cent of the children being taught by tuberculous teachers had positive tuberculin reactions. Among the pupils of a tuberculous teacher reported by Frost, 71 per cent reacted positively whereas only 11.4 per cent of children in adjacent districts taught by nontuberculous teachers were positive to the test. More recently, the Jordans, Peck Burns Slater and many others have called attention to the seriousness of the situation.

THE PREPARATION

The first step by way of preparation for such a survey is to give proper information to various groups regarding its necessity. In Minneapolis, sufficient agitation had aroused the school board so that a health certificate was required of all teachers in October 1921. For such certification however the requirement of the tuberculin test and x-ray films of the chest seemed too drastic. In fact we did not then thoroughly appreciate their significance. Therefore, certificates in some instances seemed almost worthless. As time passed much publicity was given this problem before medical and nursing organizations, school boards, educational associations, parent-teacher associations and numerous other organizations in various parts of the country. Not infrequently the necessity for adequate periodic examinations for tuberculosis of every employee of the school system and every school child was called to the attention of the school board of the city of Minneapolis. The members of this board knew that every year teachers left their work because of advanced tuber-

Prepared with the aid of a grant from the Medical Research Fund of the University of Minnesota.

Read before the Joint Session of the Mississippi Valley Conference on Tuberculosis and the Mississippi Valley Sanatorium Association Cedar Rapids Iowa Sept 28 1934.

culosis. Often they had taught until the very day the advanced disease was detected. One such case resulted in action by the parent-teacher association of that school which appointed a committee to confer with the superintendent of schools. As soon as enough publicity has been given the problem so that the various members of the community understand that it should be solved, it is time to ask for definite action of certain groups.

First the problem must be discussed with the local medical society and definite action taken by that organization. The director of hygiene of the Minneapolis school board secured the approval of the local medical society to recommend that the board take action to determine as far as possible the exact tuberculosis situation among its employees. Therefore, Feb 25, 1933, the school board adopted an order as follows: "Your Committee on Compulsory Physical Examinations recommends that between this date and the opening of school next September, all teachers and other employees of the Board of Education who come in contact with the school children submit to a Mantoux skin test; these tests to be applied at the expense of the Board under such arrangements as the Director of Hygiene shall make."

April 24, 1933, this order was modified by the adoption of the following: "That between this date and the opening of schools next September, all teachers and other employees of the Board of Education who come in contact with the school children submit to a Mantoux skin test, and if positive submit a single x-ray film of the chest, or in lieu of a skin test submit a single x-ray film, to the Director of Hygiene, all tests and x-rays to be done at the expense of the Board under such arrangements as the Director of Hygiene shall make."

The second order permitted the option of x-ray films of the chest in lieu of the skin test required by the previous order. No sooner were these orders issued than the obstructionists of all health measures issued protests, which resulted in the board modifying the order on May 8, 1933, as follows: "On May 8, 1933, the Board of Education extended the time in which employees shall submit to a Mantoux skin test or furnish an x-ray film of the chest, to December 31, 1933."

Extension of time granted by the third order of the board met the objection of many teachers that their more or less exhausted condition, following the arduous duties of the school year, might result in a positive skin test, whereas, after a summer of rest the test was more apt to be negative. This, of course, was not founded on fact but it was conceded in order to allay the unrest that prevailed as a result of the original order of the board.

THE PROCEDURE

Having secured the approval of the local medical society and the order having been granted by the school board, we were ready to proceed with the administration of tuberculin tests and the preparation of x-ray films of the positive tuberculin reactors, in addition to those who refused the tuberculin test. Here we immediately met with difficulties because of rumors that were disseminated among the teachers concerning the great danger of the tuberculin test. Some were falsely told that tuberculin contains the germs of tuberculosis and that therefore they might contract the disease through the test. Another false rumor was that the tuberculin

test would reactivate latent lesions in the body and would cause illness. Another was that administering tuberculin was being done for the purpose of eliminating teachers from the schools. This was based on the fact that there had been previous reductions in salaries and some discussion about decreasing the number of teachers. Other teachers were told that approximately 100 per cent of human beings would react positively to the test; therefore, why should they submit to it? This statement, of course, was based on personal opinion, as no one in this community had ever administered tuberculin tests to such a group to determine the actual facts.

We frequently heard the following: "These are times of depression, why waste tax money examining healthy teachers?" "They can't use us for guinea pigs to solve some of their silly theoretical problems." The old standby of interference with personal liberty was used by some. "We're all taxpayers. We've got our rights." Several stated that they had friends in city, county or state politics who would see to it that all connected with this "outrage" would lose their jobs. Numerous other equally false and absurd rumors and statements were extant.

Many of the teachers had no first-hand knowledge of tuberculosis and became somewhat alarmed. Therefore, when the time arrived to begin the administration of these tests only a very small percentage of the teachers in the first school visited submitted. They preferred to have only the x-ray film. Before we had visited many schools, new rumors flew thick and fast and were altogether beyond count. There were rumors that rose from fright that the test had already caused gangrene and loss of arms of some of the teachers, that it had caused blindness that it had caused incapacitation. Some teachers were of the firm belief that the tests were being given in order to make them ill so that others out of work might take over their positions. There were the sly rumors, the most outstanding of them all being that tuberculin acted as an emmenagogue, causing profuse uterine hemorrhage. None of the persons were so disloyal as to give us the names of the injured parties. However, one example of the probable source of these rumors was traced by good fortune, this teacher complained of a swelling of her arm from the fingers to the shoulder to twice normal size, we were unable to confirm this even by calipers, the arm was quite normal in size and the test was entirely negative. We found another teacher with a most peculiar reaction to the testing, she submitted very placidly to the injection of the tuberculin, walked out into the hall, and began to "suck out the poison" we had injected. Her arm was actually traumatized before she desisted.

In the fall of 1933 a higher percentage of teachers submitted to the test as the rumors became fewer and fewer and the attitude of the teachers steadily improved. However, some refused the test for more logical reasons. We rather frequently had teachers refuse with statements such as "My sister had tuberculosis. She's perfectly well now but I would prefer to have the x-ray examination rather than the skin test." Another would say, "I was tested for this some time ago and had a positive reaction so I do not care to be tested again." There were a few persons who reported having been treated for tuberculosis. These persons felt that application of the Mantoux test was unnecessary and submitted x-ray films of the chest in lieu of the test.

The plan outlined for carrying out the orders of the board provided for the administration of the intracutaneous test (Mantoux) in the school buildings, thus working the least inconvenience possible on the personnel. A physician and a nurse visited each building and applied the test to all employees who wished to submit. Arrangements had been made with the local radiologic society for the taking of x-ray films of the chests of all teachers and others concerned who were authorized by the school board to have such films made. Teachers who declined the skin test were issued authorization slips for the making of the x-ray films, and persons whose tuberculin tests proved positive were issued a similar authorization. These films, when made were forwarded to the hygiene department.

An option in this procedure was offered permitting teachers to have the tuberculin test applied by their private physicians, a report of the result, certified over the physician's signature, to be sent to the director of hygiene. Further, the personnel was permitted to submit x-ray films of the chest taken by physicians of their own choice. These options were exercised at the expense of the teacher. All other costs were borne by the school board.

The records of all tuberculin tests applied and all x-ray films of the chest submitted under board author-

by the school nurses, 91 per cent of the fifty-five being positive.

In the Mason City schools, Peck found that 55.67 per cent of the teachers reacted positively to the tuberculin test while of those who were tested in Ames 28.6 per cent reacted positively. He finds that approximately 50 per cent of the teachers of Iowa have been infected. Cox reported that 40.6 per cent of teachers tested in the state of Washington were found to be positive tuberculin reactors. The Jordans found that 49 per cent of their group in western Minnesota were positive.

Nineteen of our negative reactors had x-ray films for various reasons, and eighteen of these presented no lesions while one showed evidence of calcification in the right hilus. In order to secure uniformity, all of the films were interpreted by one of us and the results have been grouped in table 1. Among the positive tuberculin reactors, fifteen did not have x-ray films because of having left the school system before films were made. On the other hand, nineteen who had negative tuberculin reactions also desired to have x-ray films.

Thus, among 2,466 who had x-ray films made of the chest, 1,453, or 58.98 per cent, showed no evidence of disease, while two showed evidence of scoliosis and two evidence of substernal thyroid. Forty-four showed evidence of abnormality in cardiac outline. These were also advised to see clinicians for final diagnosis and any therapy that might be indicated.

There was evidence of increased bronchovascular markings in 175 instances. Some of these persons were later found to have suffered from asthma and some to have had infections of the upper respiratory tract or other conditions.

Sixty-six presented evidence of fibrinous pleurisy as indicated by obliteration of the costophrenic angle, diaphragmatic adhesions, and so on. Here again it is impossible from the tuberculin test and the x-ray film to determine the clinical significance of such conditions. In twenty-nine cases there was evidence of coexisting first infection type of tuberculosis and fibrinous pleurisy.

There was questionable evidence of the first infection type of tuberculosis in eighty-five cases, while in 532 others there was more definite evidence of the first infection type of tuberculosis. In this group with evidence of the first infection type is included those who have definite evidence of calcification in the hilus region and Ghon tubercle formation, as well as some who presented evidence of fibrous strands extending from the hilus region into the lung parenchyma, and definite enlargement of the hilus region.

Great care was taken to avoid interpreting shadows cast by blood vessels and other normal structures in the hilus region as evidence of calcium. We are thoroughly cognizant of the fact that small calcium deposits are often overlooked in the hilus region since so many more have been reported at the postmortem examination by Miller and others than could be detected by antemortem x-ray film examination. The significance of definite evidence of calcium deposits in the parenchyma or hilus region has only recently been appreciated. The pathologists have taught that they should no longer be looked on or even spoken of as representing "healed" lesions. The x-ray film usually gives no information whatever of what is transpiring within and

Evidence of parenchymal lesions	78

ization became the property of the school board. Reports on tuberculin test readings and reports on x-ray readings were made, in writing to each individual concerned and forwarded under seal, making them strictly confidential.

While one of us administered most of the tests, which consisted of a single dose containing 0.1 mg. of tuberculin, interpretations were made after the forty-eight hour interval by school nurses. There might therefore have been a greater personal error than there would have been had a single person been delegated to the task.

THE RESULTS

Altogether, 2,190 of the personnel were tested with tuberculin and 1,384 elected an option. Of the 2,190 persons tested, 1,112 were definitely negative and 1,078 (49.22 per cent) were positive reactors. We were unable to retest each negative reactor with 10 mg. of tuberculin, since we were forced to simplify our procedure as much as possible and therefore may have missed some reactors. It was rather interesting to note the variation in the incidence of positive reactors in the different schools. Excluding the schools in which there were fewer than five teachers (two of these schools were 100 per cent negative) our lowest figure was 10 per cent positive out of ten teachers tested. Our highest reading was 82 per cent positive out of twenty-three persons tested. The highest group incidence was given

immediately surrounding these deposits. This can be determined only by the pathologist. Therefore, none of the teachers in this group received a report to the effect that they had "healed" lesions.

In seventy-eight cases there was definite evidence of parenchymal disease. These have been subgrouped in table 2, only on the basis of probabilities. Because of the fact that the reinfection type of pulmonary tuberculosis is more frequently found in the upper half of the lung field, and other lesions such as pulmonary abscess or bronchiectasis more frequently occur in the lower half, one is reasonably safe in considering the former group of shadows as probably due to tuberculosis. Therefore, since clinical examinations could not be conducted by us, all persons with parenchymal lesions were advised to consult their physicians for completion of the examination and final diagnosis.

RECOMMENDATIONS

We are thoroughly cognizant of the fact that the tuberculin test and one x-ray film examination of positive reactors does not constitute complete examination for tuberculosis. We are also cognizant of the fact that an x-ray film examination alone does not constitute diagnosis, it only provides evidence that may be

used by the clinician in conjunction with history, physical examination, laboratory examinations and even bronchoscopic examination, in arriving at final diagnosis and determining whether the shadows revealed indicate disease of clinical significance. We do feel, however, that the best method of screening out cases for such examinations is through the use of the tuberculin test and the x-ray film. As it was not practical for the school board to carry out the further phases of the examination, reports of the results with brief explanation, were sent to the teachers and other employees. Without exception when parenchymal shadows, changes in cardiac outline, or any other finding that might be significant was present clinical examinations were advised. In order to keep a check on those who had parenchymal lesions that were probably due to tuberculosis, periodic roentgen examinations have been requested at stated intervals, the films to be submitted to the director of hygiene of the school board and to be compared with previous films. This ruling was made in order to protect the teacher herself and her pupils in the event that she does not have or fails to secure the services of a clinician to keep her lesions under close observation and recommend treatment or isolation, if necessary.

The director of hygiene has interfered in no way with the practitioners of medicine in such cases. In fact, it is not the duty of the school board to treat but it is definitely the duty of this board to make sure that

their employees do not disseminate tubercle bacilli in line of duty. In such a survey there is always the danger that the school board will be too drastic in dealing with those employees found to have parenchymal shadows. Most of the members of school boards are not trained in medicine and therefore are not in positions to differentiate between the lesions that are dangerous at one time and safe at another from the standpoint both of the individual and of her associates. Moreover, they are often fearful of public opinion. For this reason, every finding whether normal or abnormal in such a survey should be kept strictly confidential. On the basis of our experience we are of the opinion that even the tuberculin test should be applied on a part of the body which is not visible to the other teachers and pupils and that even the report on the test should be made only to the individual tested.

All too often in survey work the observations have not been treated confidentially and teachers have been subjected to mistreatment. We cite the case of a teacher employed in a small city where tuberculin tests were administered to all the teachers and the positive reactors had x-ray films made of their chests. This particular teacher reacted positively, and the film showed evidence of disease in one lung which proved to be tuberculosis. It had not yet caused any symptoms and before the examination she was wholly unaware of its presence. Nevertheless it was obviously a progressive type of lesion. She immediately took a leave of absence and had treatment instituted. When her physician observed that she was able to return to work, the fact was discovered that the information concerning the condition found at the time of the survey had not been treated confidentially. Almost every one in the community knew what had been found, and although the superintendent of schools was willing to have her return, members of the school board and the general public without a clear understanding of tuberculosis, protested to such an extent that her return had to be postponed from time to time until she eventually sought employment elsewhere.

We would contrast this teacher's case with that of another from a small city who because of mild symptoms, of her own accord, sought an examination of the chest. This revealed quite extensive tuberculosis, whereupon she conferred with the superintendent, who with her private physician treated the condition confidentially. She undertook treatment similar to that administered to the teacher cited, and in due time her physician recommended that she return to work. He informed the superintendent of her condition and she has returned with no stigmas. She is still under close observation and is a safe associate for other teachers and the pupils whom she teaches.

One of the objects of seeking out cases of tuberculosis among teachers is to enlist the support of the members of their profession in the campaign against tuberculosis. When teachers know that, even though they are found to have disease which threatens their future and makes them menaces to their associates, they will later be treated justly by their school board, they will be much more willing to submit to examination. The fear will be removed and they will enter wholeheartedly into the campaign of finding and treating adequately cases of tuberculosis not only among members of their own profession but also among the pupils whom they teach, as well as the families of these pupils. Indeed the employees of the school board having sub

mitted to a procedure intended to protect children against tuberculosis, might be expected to demand that the children be examined in order that they be insured against exposure. The examination of all school children is being considered in many places.

In the Minneapolis survey, the teachers have been treated fairly. There has been great effort put forth to keep the information concerning them confidential. Not a single teacher has lost her position because of a positive tuberculin reaction. One person found to be disseminating tubercle bacilli was required to take leaves of absence while treatment is being administered. Other teachers are being treated and kept under close observation because of lesions discovered through the compulsory examinations, but none will be required to give up work unless the lesions progress to the stage at which they may spread tubercle bacilli to their associates and for their own good more drastic treatment becomes necessary. This action on the part of the director of hygiene of the school board has revolutionized the attitude of the Minneapolis teachers concerning compulsory examinations. There are a few, of course, who are prejudiced against most health measures, but the attitude of many who were originally opposed has changed until now the personnel generally is in accord with the health movement—so much so in fact that many who had complied fully with the order demanded that thirty-three who have been negligent or reluctant to comply be compelled to submit at once.

Thus, the superintendent of schools at a meeting of the school board recommended that the thirty-three persons who had failed to comply with the orders to date be given until Oct. 1, 1934, to meet these requirements, and that those who had not complied by that date be suspended from their positions. Even though they are teachers and are well informed on the subjects they teach, they may have little information regarding health. Again, some are influenced by religion or are cultists. We do not know whether any of the thirty-three belonged to the foregoing groups. We would rather believe that their failures to comply with the order was due to procrastination. Be that as it may, all but one finally were examined and the majority of our teachers and other employees now manifest an intelligent attitude toward health work, which to us is an expression of sincerity in their life work.

COST OF SURVEY

An all-absorbing question is the cost of this survey. In all, 2,201 tuberculin tests were administered and interpreted, of which number 102 were not paid for by the school board. 2,476 x-ray films of the chest were submitted, of which number 238 were not paid for by the school board as a part of the survey cost. Some of these 238 films were taken at the Minneapolis General Hospital. The records of the department of finance of the school board show an expenditure of \$5,525.50.

SUBSEQUENT OCCURRENCES

This work was undertaken purely as a survey and therefore was approved by the local medical society. It interfered in no way with the private practice of medicine since practically none of the examinations would have been made without the order of the school board. Moreover, it is not contemplated that the work will be repeated at the expense of the school board but rather at the expense of each employee through

physicians of their choice. This is now in effect for all new employees.

Following such a survey there will be occurrences, which, not understood by opponents, will be used by them to cast reflections on the work. There still is lurking in the minds of many people the idea that tuberculosis must be contracted in infancy or childhood despite the abundant evidence to the contrary. Therefore many people still believe that if an examination is made in adult life and no tuberculosis is discovered that person is safe from future attacks of this disease. One such case is that of a clerk who reacted negatively in May 1933 and then spent the summer on a farm with an uncle who had open tuberculosis. She returned to her position in the fall apparently quite well. Jan. 10, 1934, she had a pulmonary hemorrhage and her x-ray film revealed shadows suggestive of moderately advanced pulmonary tuberculosis of the exudative type. Her tuberculin reaction was positive in the 1:100 dilution. This case has not invalidated our opinion of the negative reaction in the least. While we realize that the test is not 100 per cent accurate and that this woman might have been in the small group who had the disease without or with only minimal degree of allergy, it must be remembered that her exposure on the farm during the summer might also have resulted in her disease. We do feel that this case brings out the fallacy of the belief held by many people that the statement by a physician "you have no tuberculosis" is a guaranty that they will not develop the disease at some later time.

Another case is that of a teacher whose x-ray film showed very slight change in the left second interspace. There were small densities present, which we interpreted as evidence of the first infection type of tuberculosis. However, within a few months this teacher suddenly fell ill and was found to have extensive disease over the left upper lung field. We are inclined to believe that this was a case of tuberculous pneumonia resulting from the rupture of a caseous lymph node into the bronchial tree. Thus a person who is negative to the tuberculin test today may be exposed to some one suffering from tuberculosis tomorrow and have frank pulmonary tuberculosis within six to twelve months. Another may have lesions which appear insignificant but which through rupture or rapid spread may cause serious illness in a few days or weeks. Such cases show the great need of requiring examinations of teachers periodically. As a result of the follow-up work, three other persons have been found to have tubercle bacilli in the sputum, thus making a total of six open cases of tuberculosis already discovered directly or indirectly through the survey.

EDUCATIONAL ADVANTAGES

One of the objects of such a survey is to interest the teaching profession in tuberculosis control. During and immediately after the survey, all are interested. This is the time to apply the old principle in pedagogy that the best time to teach is when the individual is personally interested in the subject. Therefore, many teachers who had never thought about tuberculosis became interested in the disease and sought information. For example, they wanted to know just what tuberculin is. Here was an opportunity to explain how it is made and to disprove the false statements so frequently made about it, particularly to the effect that it contains tubercle bacilli.

The teachers asked why one reacts positively to the test and another negatively, and here was an opportunity to discuss sensitiveness of the tissues to tuberculo-protein, which results from the growth of tubercle bacilli in the human body. One also had an opportunity to call attention to the rapid decrease in the incidence of positive reactors and to point out to them how it may be possible in time to protect every one so that very few or none will have the handicap of sensitiveness to tuberculin. They asked what a positive reaction means and here was an opportunity to explain to them that it means an exposure to some one with tuberculosis at some previous time and that tubercle bacilli have entered, so that at least one focus of tuberculosis exists somewhere in the body, and to point out that this constitutes a double health liability and that the old idea that a positive reaction is an asset is erroneous. Here one can also point out the great value of the tuberculin test in tracing the source of the infection and explain that the exposure may have continued to the present time and may be found among close associates apparently in good health. One teacher refused the test without giving any reason. Further examination revealed definite evidence of disease after which she called our attention to the fact that at one time her father had been a sanatorium patient but for several years had refused to have further examinations. It was learned that while he was in the institution he had advanced tuberculosis of the chronic type, with cavitation. She now insisted on a reexamination of her father, which showed very definite evidence of tuberculosis. We understand that several teachers who reacted positively to the test became interested enough in the source to have various members of their families examined for tuberculosis by their physicians.

Teachers asked whether one can determine from the tuberculin test if an individual has a progressive disease. Here was an opportunity to call their attention to the strong natural protective mechanism of the human body and to point out how this in the majority of cases walls off the bacilli so that they never cause illness. Attention must also be called to the fact that a minority, consisting of from 10 to 20 per cent of positive reactors, will at some time be ill from tuberculosis.

When the x-ray film interpretations are presented to the teachers, other questions arise in their minds. Some ask whether disease always attacks the lungs and here one has an opportunity to explain that tuberculosis may attack almost any part of the body and the fact that the x-ray film shows no evidence of disease in the lungs of a positive tuberculin reactor is no indication that tuberculosis does not exist. Others will ask whether the x-ray film is infallible, even when disease exists in the lungs. Here one has an opportunity to explain that considerable disease may exist without being visualized by x-ray film examination, that the disease area must be large enough so that it can be plainly seen with the naked eye before it will cast a shadow on an x-ray film which can be seen by the naked eye. One must explain that, while much may escape detection on an x-ray film, when an area of disease in a lung is sufficiently large to threaten the immediate future of the individual and to be a menace to that person's associates it will nearly always cast a shadow that can be visualized on the x-ray film. However, other phases of examination are necessary to determine the exact nature of the disease that casts the shadow. Still another

teacher will inquire as to whether the x-ray film will determine with accuracy as to whether a lesion is progressive. Here one has an opportunity to explain that x-ray film work is purely a matter of studies of lights and shadows and that there is nothing sufficiently characteristic about shadows so that one can determine with a high degree of accuracy as to whether a lesion is progressive, but that periodic x-ray film examination and comparisons give one an opportunity to study the size and nature of the shadows from time to time and in this way progressiveness of a lesion may be very definitely determined.

SUMMARY

Observation has shown that a very definite tuberculosis problem exists among teachers and other employees in the schools of this country. Therefore many school boards are requiring examinations of teachers. Large numbers of physicians throughout the country will be consulted or called on to take part in these examinations in their offices and elsewhere.

The preparation for the examination of teachers in any community must begin with the approval and active support of the local medical society, followed by the proper issuance of an order by the school board. In many places the latter probably will not be necessary, as the teachers will voluntarily submit to adequate examinations by physicians of their choice. The procedure is very simple, consisting of administration of the tuberculin test and the making of x-ray film examinations of all positive reactors. These act only as screens to determine which teachers should have complete clinical examinations by their physicians.

In our survey one employee was found to be disseminating tubercle bacilli and sixty-eight others presented lesions that were probably due to tuberculosis of the reinfection type. Subsequent examinations have brought to light five more open cases of tuberculosis. Numerous other workers have found open tuberculosis previously unsuspected among teachers, when compulsory examinations were made.

Teachers found to have open tuberculosis should be given leaves of absence until treatment aids in rendering the sputum negative and the lesions are brought sufficiently under control so that it is safe for the teacher to return to her work. Those who have lesions which are not progressive should be examined periodically and if at any time the lesion is found to progress, treatment should be instituted. All observations should be treated confidentially, both in the physician's office and elsewhere.

The chief advantages of such a survey are that First disease may be detected before it has produced significant symptoms and when it can be treated successfully in a short time, thus saving the teacher a long period of inactivity from work. Such cases by adequate treatment, may be prevented from breaking down so as to be a menace to the children and other teachers. Thus, the environment so far as tuberculosis is concerned becomes much safer from the standpoint both of the teacher and of the child. Second compulsory examinations often lead to investigation on the part of the teacher so that she becomes informed concerning the contagious nature of tuberculosis. Many such teachers become enthusiastic workers in the tuberculosis control program. This should lead ultimately to the enlistment and the support of great educational associations, which will be a valuable acquisition to the forces against tuberculosis.

THE DECLINING DEATH RATE FROM
TUBERCULOSIS IN CHILDRENAN ANALYSIS OF TUBERCULOSIS DEATHS IN
MINNESOTA FROM 1915 TO 1932RUTH E. BOYNTON, M.D.
MINNEAPOLIS

There is a great deal of interest both in this country and in foreign countries in the prevention of tuberculosis in infants by the use of BCG vaccine. Proponents of this method of preventing tuberculosis feel that the immunity produced by BCG vaccine will reduce the incidence of the disease in infants and young children who are intimately exposed to tuberculosis, thus reducing the mortality rate in this age group.

The material presented here is not intended to express any opinion for or against the efficacy of specific vaccination against tuberculosis. It seemed of interest, however, to analyze the mortality rates from tuberculosis in children over a period of years in a state where no attempts at BCG vaccination have been

MORTALITY RATES FROM ALL FORMS OF
TUBERCULOSIS

Table 1 shows the number of deaths and the death rates from all forms of tuberculosis by age groups for each year from 1915 to 1932. Of a total of 2,946 deaths in children under 15 years of age, 656, or 22.3 per cent, occurred in children under 1 year of age. In 1915 32 per cent of the deaths in children under 15 occurred in the group under 1 year, in 1926, 17 per cent, and in 1932, only 14.5 per cent.

This downward trend is shown graphically in chart 1. Compared to the decline in mortality from tuberculosis in all ages in Minnesota, the greater decrease in children under 1 year of age is striking. Wallgren,² citing the decrease in mortality from tuberculosis in children in Gothenburg, Sweden, as evidence of the value of BCG vaccination, says "It should be noted that the general tuberculosis death rate especially from pulmonary tuberculosis has not shown the same downward tendency. This signifies that the number of the sources of infection has not, broadly speaking, decreased in proportion to the decrease in the number of deaths

* Rates per hundred thousand of population in the age group

made, and to compare the trend in mortality here with that in a locality where vaccination has been used.

Data were obtained from the tuberculosis mortality cards of the Division of Preventable Diseases of the Minnesota Department of Health and mortality rates computed per hundred thousand children in each age group. The method of estimating the population for each age group has been described elsewhere.¹

All deaths from tuberculosis occurring in children under 15 years of age for the eighteen-year period 1915-1932 were tabulated. The deaths for each of these years were divided into the following age groups: under 1 year, 1 to 2 years, 2 to 3 years, 3 to 4 years, 4 to 5 years, 5 to 10 years and 10 to 15 years. The deaths for each age group were further classified according to the following types of the disease: tuberculous meningitis, pulmonary tuberculosis, miliary tuberculosis, lymph node tuberculosis, and bone and joint tuberculosis.

The numbers of deaths from lymph node and bone and joint tuberculosis were too small to make any comparison of rates reliable. Therefore, only the first three types will be discussed.

from tuberculosis in infants'. The same difference between the tuberculosis death rate in the general population and in infants exists in Minnesota, although no use has been made of BCG vaccine.

A comparison of mortality rates from one year to another may be misleading unless based on large numbers of deaths, hence the average death rate from all

TABLE 2—Death Rates from Tuberculosis in Children in
Minnesota by Three Year Periods

Period	Years	Total	Under 1 Year	1-2 Years	2-3 Years	3-4 Years	4-5 Years	5-10 Years	10-15 Years
1	1915-1917	36.6	155.7	52.3	43.0	21.1	17.3	10.7	30.0
2	1918-1920	25.8	88.1	54.1	38.8	26.4	24.4	10.4	24.0
3	1921-1923	20.9	73.2	49.7	19.6	18.5	12.7	11.5	16.5
4	1924-1926	18.1	61.7	38.8	17.7	15.0	11.7	9.4	16.8
5	1927-1929	10.0	43.5	29.4	27.0	17.5	7.3	0.2	13.0

forms of tuberculosis by each three year period was computed and is presented in table 2. This again shows a downward trend of mortality for all age groups, with the group under 1 year showing the greatest decline. A comparison of the rate for the period 1915-1917

From the Students' Health Service and Department of Preventive Medicine and Public Health, University of Minnesota.
1. Boynton, Ruth E. Tuberculosis Mortality Among Children in Minnesota. *Am. Rev. Tuberc.* 16: 379 (Oct.) 1927.

2. Wallgren, Arvid. Value of Calmette Vaccination in Prevention of Tuberculosis in Childhood. *J. A. M. A.* 103: 1341 (Nov. 3) 1934.

with the rate for the period 1930-1932 shows that for all children under 15 years of age there was a decrease of 72 per cent for children under 1 year a decrease of 88 per cent, while for all ages there was a decrease of 58 per cent. This is shown graphically in chart 2.

A comparison of these figures with those reported by Wallgren shows first that the mortality in Wallgren's

Chart 1—Death rates from all forms of tuberculosis in Minnesota 1915-1932 (logarithmic scale)

group from 1912 to 1916 was 430 per hundred thousand, while the Minnesota rate for approximately the same period was 1557 per hundred thousand and secondly that the mortality rates reported by Wallgren declined only 93 per cent from 1912 to 1928 while in Minnesota during the same period the rate declined 60 per cent.

TABLE 3—Mortality Rates from Tuberculosis in Minnesota by Six Year Periods

Years	Total	Under 1 Year	1-2 Years	2-3 Years	3-4 Years	4-5 Years	10 Years	10-15 Years
All forms of tuberculosis								
1915-1920	11.2	121.9	63.2	40.6	28.0	20.8	18.0	27.3
1921-1926	10.0	67.4	41.7	18.6	17.0	10.2	10.4	10.6
Actual reduction	11.7	54.5	21.5	22.0	11.0	8.6	7.6	10.7
Per cent decrease	37.0	44.7	21.6	54.2	41.2	41.3	42.2	30.2
1921-1926	10.0	67.4	41.7	18.6	17.0	12.2	10.4	10.6
1927-1932	12.0	30.8	28.1	20.6	10.5	8.6	6.0	11.4
Actual reduction	7.0	36.6	11.4	+2.0	1.5	3.6	4.4	5.2
Per cent decrease	3.9	44.3	22.1	+10.7	8.8	20.1	40.3	31.1

Wallgren reports a decline in mortality rate from 34 per thousand for 1922-1926 to 14 per thousand for 1928-1932 a reduction of 60 per cent. This he attributes largely to the use of BCG vaccine.

In order to compare the decline in rate in Minnesota with these figures of Wallgren the average rate by six year periods in the eighteen years analyzed was computed. These data are presented in table 3. In children under 1 year of age there was a reduction in the death rate of 44.7 per cent between 1915-1920 and 1921-1926, and a reduction of 54.3 per cent between 1921-1926 and 1927-1932. Although this decline of 54.3 per cent is slightly less than the decline of 60 per

cent reported by Wallgren for approximately this same period, it is significant to note that the rate of decline in Minnesota was greater during the last six years. For all children under 15 years of age the percentage decrease between the first six year period and the second six year period was 37.5 per cent, and between the second and third six year periods 35.9 per cent. As the mortality rates become lower, the percentage of decrease necessarily becomes lower as the irreducible minimum approaches.

TABLE 4—Deaths from Five Types of Tuberculosis in Children Under 15 Years of Age in Minnesota 1915-1932

Type	Total	Under 1 Year	1-2 Years	2-3 Years	3-4 Years	4-5 Years	5-10 Years	10-15 Years
Meningitis	128	170	230	133	112	78	173	102
Pulmonary	374	234	213	221	240	106	418	667
Miliary	70	0	0	8	10	11	23	34

Bone and joint	20	0	0	1	2	1	3	3
Total	100	2	343	2	183	117	350	00

Percentage represent the proportion of deaths in each age group caused by the particular type of tuberculosis.

Table 4 presents the total number of deaths from each of five types of tuberculosis for the period 1915-1932. The three types of tuberculosis causing the greatest number of deaths of children in this age group in the order of their importance are tuberculous meningitis, pulmonary tuberculosis and miliary tuberculosis. In the entire group under 15 years of age, 51.2 per cent of the deaths were caused by tuberculous meningitis, 37.4 per cent by pulmonary tuberculosis, and 7.9 per cent by miliary tuberculosis. In children under 5 years of age tuberculous meningitis caused from 61 per cent

Chart 2—Mortality rate of 1915-1917 compared with rate for 1930-1932 by age groups

to 67 per cent of all deaths while in the 10 to 15 year old group pulmonary tuberculosis caused 66.7 per cent of the deaths. This is shown graphically in chart 3.

TUBERCULOUS MENINGITIS

The decline in mortality from tuberculous meningitis is shown in table 5. For children under 15 years of age there was a decrease of 81 per cent between 1915-

1917 and 1930-1932 and in children under 1 year a decrease of 90 per cent. In table 4 it was seen that this form of tuberculosis caused more deaths than any other form in children under 15 years. Likewise the greatest reduction in mortality occurred in this type of the disease, the largest reduction occurring in the group under 1 year of age.

Chart 3—Relative importance of various types of tuberculosis in children. Percentages show the proportion of deaths in each age group caused by each type of the disease.

TABLE 5—Mortality Rates from Tuberculous Meningitis in Children in Minnesota

Period	Years	Total	Under 1 Year	1-2 Years	2-3 Years	3-4 Years	4-5 Years	5-10 Years	10-15 Years

Per cent decrease 1915-1917 to 1930-1932		60	81	+28	55	20	+31	66	64

PULMONARY TUBERCULOSIS

Although pulmonary tuberculosis causes a greater percentage of deaths in the older age groups, this form of the disease also shows the highest death rate in infants under 1 year of age (table 6). The rate of reduction, however, has been greatest in the group under 1 year of age (81 per cent). For the period 1930-1932 the rate of 60 for infants under 1 year is approximately the same as for the 10-15 year group, 61.

MILIARY TUBERCULOSIS

The actual number of deaths from military tuberculosis is smaller and the death rates therefore lower than for tuberculous meningitis and pulmonary tuberculosis. Nevertheless there is the same downward trend in mortality rates for all children, with the most marked decrease in the group under 1 year of age (table 7). Since military tuberculosis is usually the result of a massive infection, this reduction in mortality rate is evidence of the protection given children by the earlier diagnosis and isolation of infectious cases.

TUBERCULOSIS—BOYNTON

Petroff³ has said 'The most convincing proof of the effectiveness of the campaign against tuberculosis adopted years ago is the decline year after year in the death rate from this disease.' As this analysis of deaths from tuberculosis in Minnesota shows greater progress, as measured by mortality rates has been made in controlling tuber-

TABLE 7—Mortality Rates from Military Tuberculosis in Children in Minnesota

Period	Years	Total	Under 1 Year	1-2 Years	2-3 Years	3-4 Years	4-5 Years	5-10 Years	10-15 Years

2	1918-1920	1.5	11.3	1.9	0.0	1.2	0.0	0.5	1.2
3	1921-1923	1.0	7.8	3.8	2.4	2.9	1.2	0.8	1.1
4	1924-1926	1.0	4.4	2.9	1.7	1.1	1.7	0.2	0.5
5	1927-1929	1.2	5.2	3.0	3.0	1.4	0.6	0.4	0.4
6	1930-1932	0.9	0.7	3.7	2.1	2.0	2.8	0.7	0.2

culosis in children than in older people. This is especially true of children under 1 year of age. In the future vaccination of some sort may be used more extensively in the control of tuberculosis in young children. It seems evident, however, that a thorough and consistent general program for the control of tuberculosis, on the basis of our present knowledge of early diagnosis, isolation and treatment has caused as great a decline in mortality as has occurred when specific vaccination has been used.

SUMMARY

1 In Minnesota where BCG vaccination has not been tried, tuberculosis mortality rates in children are lower and have decreased at a more rapid rate than that reported by Wallgren in Gothenburg, Sweden, with the use of BCG vaccine.

2 From 1915 to 1932 inclusive, 2,946 deaths from all forms of tuberculosis in children under 15 years of age were reported in Minnesota. In 1915 32 per cent of

Chart 4—Death rate from tuberculous meningitis, pulmonary tuberculosis and military tuberculosis by six-year periods and by age groups.

the tuberculosis deaths under 15 years occurred in the group under one year, while in 1932 only 14.5 per cent of the total deaths were in this group.

3 Although the mortality rate under 1 year has decreased more than 80 per cent during this eighteen

³ Petroff, S. A. Antituberculous Vaccination. New England J. Med. 211: 6-7 (Oct 11) 1934.

year period, the death rate remains higher for the group under 1 year than for any of the other groups under 15 years

4 Between 1915-1917 and 1930-1932 the mortality from tuberculosis declined 72 per cent for all children under 15 years of age, 88 per cent for infants under 1 year, and 58 per cent for the general population in Minnesota

5 Between 1915-1920 and 1921-1926 there was a decrease of 37.5 per cent in the tuberculosis mortality in children and between 1921-1926 and 1927-1932 a reduction of 35.9 per cent

6 The types of tuberculosis causing the greatest number of deaths in children in the order of their importance were tuberculous meningitis, pulmonary tuberculosis, and milary tuberculosis. The largest percentage of deaths from tuberculous meningitis occurred in children under 5 years of age and from pulmonary tuberculosis in those between 10 and 15 years of age. The highest mortality rate from both types was found in the group under 1 year of age. There was the greatest percentage of reduction in mortality rate in both types of the disease in children under 1 year of age

7 Lymph node and bone and joint tuberculosis are negligible as a cause of death in children under 15 years of age

RELAPSING FEVER IN THE UNITED STATES

JAMES O. GILLESPIE, M.D.

Captain Medical Corps U. S. Army

SAN ANTONIO, TEXAS

Prior to 1930, relapsing fever was practically unknown in the United States except for a few sporadic cases in Colorado and California, having last been encountered in epidemic proportions along the eastern Atlantic seaboard during the period 1869-1871. The report¹ of cases occurring in Texas in which the vector was proved to be the tick *Ornithodoros turicata* stimulated interest in this important disease with the result that in that state and California it has been reported with increasing frequency. In Texas,² data have been collected on 258 cases that have occurred during the last five years. On the basis of published proved cases the disease is endemic in Colorado, California, Arizona, Texas and Kansas. It is my purpose in this paper to bring to the attention of physicians a disease which probably is endemic throughout the entire southern half of the United States wherever ticks of the genus *Ornithodoros* find their habitat. The following cases may be considered typical of the disease as it occurs in the endemic areas.

REPORT OF CASES

CASE 1³—Mrs. P. M. K., seen, Jan. 23, 1934, complained of fever, malaise and a chill. The temperature was 103 F. The temperature remained high, accompanied by chilly sensations and she was admitted to the hospital, January 25, with a temperature of 105 F., pulse 116, and respiration rate 30. The past, personal and family histories were negative. On admission there was evidence of congestion in both lung bases and

roentgenograms revealed a diffuse bronchopneumonia throughout both lungs. The urine contained albumin and a few red and white cells. A moderate polymorphonuclear leukocytosis was present, otherwise the blood was normal. January 26 the temperature reached normal but rose to 105 F. on the 27th and then returned to normal by crisis on the 28th.

An afebrile interval of six days, during which period the patient felt quite well, was followed by a sudden accession of the fever to 104 F., February 3. The clinical picture, including the lung signs, was repeated, and this attack subsided, February 6. A slight elevation of temperature occurred on the 7th with a return to normal on the 8th.

The patient remained afebrile until February 18 and was quite free from symptoms, except for a moderate degree of weakness. The temperature rose suddenly to 103.8 F. on this date and remained elevated until the 23d. This attack was complicated by a moderately severe iritis and hemorrhagic nephritis. Following this there developed extreme pain and localized sensory changes indicating a radiculitis of the third, fourth and fifth lumbar roots. Spirochetes of the genus *Borrelia* were demonstrated in the blood and 0.3 Gm. of nearsphenamine was administered intravenously, February 20. February 28 symptoms referable to the iritis and nephritis were repeated in a milder form but a second injection of nearsphenamine was not made, owing to severe retrobulbar pain, following the first injection, with a subsequent paling of the mesial aspect of the optic disks.

March 12, after an afebrile period of seventeen days the final relapse occurred. The temperature rose to 103 F., and 0.6 Gm. of nearsphenamine was administered intravenously. The temperature became normal within forty-eight hours and no further symptoms referable to the complications were noted.

CASE 2—E. C., a white native of Texas, was a member of the Civilian Conservation Corps at Mathis, San Patricio County, Texas, in which organization he had served nine months, the past three being at Mathis in the capacity of assistant surveyor. Twenty-five days prior to the onset of his illness he had spent parts of two days at his home in Hull, Texas, about 60 miles east of Houston. During the twenty-five day period he had remained in camp, with an occasional visit to Mathis. The previous history is unimportant. The onset of the illness was abrupt, July 30, 1934, with complaints of headache, malaise, fever increasing in severity that night and the following day, requiring admission to the camp dispensary on July 31. During the morning of August 1 a light chill was noted. Small amounts of white, mucoid sputum were raised without coughing. A moderate degree of weakness was complained of. On admission to the Station Hospital, Fort Sam Houston, August 1, the patient was acutely ill, with a temperature of 103.6 F., pulse 136, and respiration rate 32. The patient was well nourished and developed, entirely rational but with a heavy apathetic appearance. The skin was clear. The tongue was moist and heavily coated with white fur. The blood pressure was 100 systolic, 60 diastolic. The remainder of the examination was negative. Within twenty-four hours after admission the temperature reached normal, but a recrudescence occurred to 100.6 F., finally reaching normal, August 5.

After an afebrile period of three days, during which time the patient felt very well except for moderate weakness, a relapse occurred. The chief complaints were severe, generalized headache, pain across the lower part of the back and legs, sluggishness and weakness. The mind remained clear. The febrile period lasted three days, the fever reaching a maximum of 104 F., pulse 130. There was no cough or expectoration during this relapse. The temperature declined by crisis and was accompanied by profuse perspiration. The blood continued to show a mild leukocytosis, with a slight increase in the polymorphonuclear leukocytes.

A second relapse occurred August 17, after an afebrile period of six days. The clinical picture was essentially the same as the first relapse except that the temperature reached 106 F. and the patient appeared more ill. After three days the relapse terminated by crisis accompanied again by severe perspiration. A light chill was noted during the febrile period. The third relapse began August 27, after an afebrile period of six days. A dark field examination of the blood was made on the 29th and numerous actively motile spirochetes of the

Survey of the Epidemiology and Clinical Manifestations of the Disease as it Occurs in Texas, read at the thirtieth annual meeting of the American Society of Tropical Medicine at San Antonio, Texas, Nov. 14, 15 and 17, 1934.

³ Report by Dr. Edgar M. McPeak, M.D., San Antonio, Texas.

genus *Borrelia* were found. On the 30th the temperature reached normal, accompanied by drenching sweats. The maximum temperature was 105 F. During the febrile periods the urine constantly contained traces of albumin and numerous granular casts. Examinations for malarial parasites were negative.

When the correct diagnosis was determined, treatment was delayed until the onset of the fourth relapse, which again occurred after an afebrile period of seven days. Except for moderate weakness and rather persistent pains in the muscles of both lower extremities, the patient had no complaints during this period. Spirochetes were demonstrated in the blood by stained smear twenty-four hours prior to the final rise of temperature. September 8, when the temperature had risen to 100.2 F, a single dose of 0.6 Gm of neoarsphenamine was administered intravenously and within twenty-four hours the temperature reached normal. A period of four months has elapsed without further recurrence. There were no complications. A transitory four plus Kahn test was noted just prior to the fourth relapse, serologic tests being entirely normal on admission and before discharge.

HISTORICAL

Historically the disease is dated to observations by Hippocrates and it was subsequently known for centuries in Europe, Asia and Africa. The first modern observations were recorded by Ratty in Dublin in 1741.

Temperature during illness in case 2

Irish immigrants are credited with introducing the disease into Philadelphia in 1844. In 1869 epidemics occurred in Philadelphia and New York. In 1873 Obermeier published his observations on the causative spirochete, which had first been seen by him in a German epidemic in 1868. The first cases⁴ occurring in native Americans in whom the spirochetes were demonstrated in the blood were reported from Colorado in 1915.

ETIOLOGY

The exciting cause is a spirochete of the genus *Borrelia*, which produces a septicemia in man. Wherever found throughout the world, relapsing fever spirochetes morphologically exhibit no constant difference, but they have been given species names based largely on differences in immunologic reactions, although this method is now considered unsatisfactory and unreliable. *Borrelia recurrentis* is the name applied to the European "species" and *Borrelia novyi* to the American. The latter spirochete was isolated from a ship steward who had recently returned from tropical America. In Europe and Asia the disease is transmitted by the body and head louse and has been associated with typhus fever and hence has been definitely related to poverty, famine, poor sanitation and overcrowding. In central and eastern Africa, South America and the southwestern part of the United States, ticks of the genus *Ornithodoros* are chiefly concerned, and the disease tends to occur in the areas in which the ticks find their

normal habitat. The tick concerned in the transmission of relapsing fever spirochetes is of the family Argasidae, genus *Ornithodoros*, of which there are numerous species. Argasine ticks are characterized by the fact that the head and mouth parts are concealed beneath the body so that as viewed from above only the legs are seen. The genus *Ornithodoros* is distinguished from the only other genus of this family, namely, *Argas*, by the rounded edge of its body.

By cytology and immunity tests,⁵ spirochetes collected from widely separated regions in Texas were found to be identical with one another and a similar study of spirochetes collected in different parts of California⁶ showed them to be identical with one another. A comparison of Texas and California "strains" has not been made. "Texas" spirochetes were found to vary in length from 6 to 25 microns, they were actively motile, with a forward and backward rotary motion, and maintained a rigid longitudinal axis in wet preparations. In stained preparations the evenly coiled structure was replaced by wavy undulations with many twisted and looped forms. Attempts at culture were unsuccessful.

As seen in Texas² the disease tends to occur in rural districts, usually in isolated regions. It is not uniformly distributed throughout the counties where it occurs but tends to be sequestered. The majority of cases occur in the late summer. *Ornithodoros turicata* spends its life⁸ within a narrowly restricted area, preferring dry sandy country, the floors of small dry caves and old uninhabited rock houses. In California, relapsing fever appears to be contracted in mountainous areas 5,000 feet above sea level. In Kansas the reported cases have occurred in rural districts. The vector concerned, as heretofore noted, has been proved to be the tick *Ornithodoros turicata* in Texas alone, but it is not unreasonable to assume that a tick of the genus *Ornithodoros* is the vector throughout the entire southwestern part of the United States when it is recalled that throughout the world wherever tick-borne relapsing fever occurs no insect vector but ticks of the genus *Ornithodoros* have been incriminated. Francis⁹ was unable to transmit relapsing fever to mice by the bite of bedbugs infected with the Texas "strain" of spirochetes.

In many cases there is no history of tick bite. Kemp and his associates⁸ stress the point that tick larvae and the smaller nymphs fill rapidly, in ten or twenty minutes, and produce a small, often painless lesion, which may be undetected by the host. These forms are infectious, as the parent tick once infected remains so for life and transmits virulent spirochetes to its progeny. Francis¹⁰ demonstrated the persistence of spirochetes in naturally infected ticks collected in caves in Texas for a period of two and one-half years. The ticks had not been fed during that interval, but five days after they were allowed to feed on a white rat spirochetes were demonstrated in the animal's blood. The mode of infection in human beings appears to be contaminative in both lice-borne and tick-borne relapsing fever in that infected coxal fluid and feces of the lice and ticks are rubbed into the wound made while feeding.

The armadillo and opossum in Texas¹¹ and the tamarack squirrel and chipmunk in California¹² have been proved to harbor spirochetes morphologically identical with *Borrelia recurrentis*. In Panama¹³ relapsing fever has been experimentally produced in man by the injection of blood from naturally infected animals. The animals mentioned may serve as reservoirs of infection in the regions named.

PATHOLOGY AND SYMPTOMATOLOGY

There have been no pathologic studies made in the United States, because of absence of material. Abroad, a parenchymatous degeneration of the kidneys, heart and liver has been noted, with a large soft spleen. The general symptomatology of relapsing fever is the same throughout the world, although variations occur as to the number and character of the paroxysms. In European relapsing fever (the louse-borne variety) the second febrile accession is usually shorter and of less severity than the first. Kemp and his associates² found that the onset of fever is abrupt, rapidly reaching 104 or 105 F, often accompanied by a chill, and with headache and muscle pain in the lower extremities and back. In the majority of their cases the febrile period lasted three days but varied from two to five. Sudden termination of the fever by crisis, accompanied by profuse, drenching sweats with a pungent odor was frequently noted. Relapses occurred at irregular intervals, varying in any one case from two to nine days. In the majority of cases the severity increased sharply in the recurrences. The pulse, unlike typhoid, is accelerated in proportion to the fever. Polymorphonuclear leukocytosis of a mild and moderate degree is usual. A rash of rose colored spots may occur on the trunk or limbs during the onset. The liver and spleen may become palpable. Nausea and vomiting with diarrhea occur in a minority of cases, constipation being a more common complication. In American cases, muscular asthenia of variable degree is the most common sequela, and hemorrhagic nephritis, iritis, cranial nerve paralysis and meningitis have been reported in a small number of cases. Throughout the world pneumonia, polyarthritides, parotitis, adenitis and abortion in pregnant women have been reported. In American

cases the mortality has been zero. As the disease occurs abroad, the average mortality varies from 2 to 5 per cent and has reached 80 per cent in certain epidemics.

DIAGNOSIS

Clinically the temperature curve is the most important single clue in the diagnosis. Dark field examination of the blood taken during a paroxysm of fever is the method of choice for the demonstration of spirochetes present in large numbers. Thick blood smears, as prepared for malarial examination, are recommended, as they increase five fold the chances of finding the spirochetes. The dried smear without fixation should be immersed in a solution¹⁴ (0.1 cc. of stock Griesa solution in from 5 to 8 cc. of distilled water) for thirty minutes, dried without blotting and examined under oil immersion. Of laboratory animals the monkey is most susceptible to inoculations from human beings. White mice and white rats are suited to routine use, an intraperitoneal injection of a drop or two of citrated blood resulting in spirochetosis in from two to three days. In the differential diagnosis, malaria is most often confused. Rat-bite fever can be differentiated only by demonstrating a spirochete quite different morphologically from *Borrelia recurrentis*. In certain respects typhus fever, typhoid, undulant fever and dengue fever show a similarity but the differences are more marked and these diseases should not present any difficulty unless they happen to coexist. A transitory positive Wassermann reaction is noted in about one fifth of the cases.

TREATMENT

The arsenicals are specific. A single intravenous injection of neoarsphenamine, 0.1 Gm for each kilogram of body weight, administered at the onset of a paroxysm, will effect a cure in practically every case. It is to be emphasized that a single maximum dose is desirable and that treatment should not be instituted during the middle or terminal stages of a febrile paroxysm or during the afebrile period, as relapses are more apt to occur, with an increased frequency of complications. A study of case reports in the American literature reveals a close correlation between inadequate dosage and relapses, often with severe complications.

COMMENTS

In the endemic areas, relapsing fever is at present of low incidence. This is due in part to the sparsely settled conditions and to the habits of the insect vector. With an increase in population and especially if infected areas become more congested as the result of grouping such as occurs in camps of the Civilian Conservation Corps or in military mobilizations, higher morbidity and mortality may be expected. Within recent years in northern Africa, Nicolle and Anderson transmitted the relapsing fever of Tunis through both ticks and lice.¹⁴ These investigators consider this disease as originally tick borne, but, having become adapted to lice, has been spread throughout the world by these widely diffused carriers.

CONCLUSIONS

1 Relapsing fever in the southwestern part of the United States is an important clinical entity and is being recognized with increasing frequency.

2 It is believed that as physicians become "sensitized" to this disease the endemic area will be found to be of much wider extent than at present.

NEW YORK

Many patients with diphtheria do not receive antitoxin until a positive laboratory report on the nose or throat culture is obtained. This is common practice, even though medical students are taught to administer antitoxin if there is even a clinical suspicion of diphtheria. Moreover it is generally agreed that, the earlier antitoxin is given in diphtheria, the better the prognosis. At present at least eighteen hours and frequently more than twenty-four hours elapse between the time a throat culture is taken and the time a report is received, and such a delay before antitoxin is administered may mean the difference between recovery and death. Since so much dependence is placed on the bacteriologic diagnosis of diphtheria, we wish to familiarize the practicing physician with a rapid and accurate method for the identification of diphtheria bacilli.

In a previous communication we described briefly our early experience with the rapid culture method.¹ Further work has shown that the new method is not only more rapid but also more accurate than the Loeffler blood serum slant method, which at present is used almost universally for the culture of diphtheria bacilli. Sole² states that a description of the method was first given by Folger at a medical meeting in Carinthia thirty-six years ago but was not published. The technic, which is extremely simple, is as follows.

Sterile cotton swabs are impregnated with undiluted unheated horse serum to which no preservative has been added.³ The swabs are then squeezed lightly against the sides of the tube to remove any surplus serum. They are removed and lightly heated over a flame to obtain surface coagulation and possibly, as

Sole states to destroy any antibodies in the serum. The swabs are then used to take the nose and throat cultures in the routine manner. Instead of being implanted on a culture medium the swabs are put in dry sterile tubes, placed in the incubator and examined at the end of two and four hours. The physician's vest pocket may serve as an incubator. At the end of the incubation period, smear preparations are made on slides directly from the swab.

OUTLINE OF INVESTIGATION

The method was investigated for its reliability in cases of clinical diphtheria and in cases showing a nasal or pharyngeal membrane of nondiphtheritic etiology. From each nasal or pharyngeal lesion investigated, two Loeffler slants were inoculated and three swabs for the rapid cultures were made. One rapid culture swab was examined at the end of an incubation period of two hours and the second at the end of four hours. The third swab was incubated four hours and then the growth was transplanted to Loeffler medium. The transplant was incubated and this culture was used for fermentation tests and virulence tests in guinea-pigs for further verification of the morphologic diagnosis. One of the two Loeffler slants inoculated directly from the lesion under investigation was sent to the Board of Health laboratory and the other examined in the hospital laboratory. Thus we could compare the results of the rapid method with two independently examined Loeffler slants, as well as with the fermentation and virulence tests. The laboratory data were then correlated with the clinical diagnosis.

We used the following two types of cases in our study: (1) clinical diphtheria, and (2) those with membranous lesions in the pharynx due to streptococcal infections. Vincent's angina or leukemia. The second group served as a control series. The results in each group have been tabulated separately. We found as Sole² reported, that in cases of clinical diphtheria about 80 per cent of the rapid cultures show diphtheria bacilli at the end of two hours. We again corroborated Sole's work in finding that the optimal incubation period is four hours, and therefore only the results with the four-hour culture are recorded in the tables.

RESULTS

Cases of Diphtheria—The results in sixty-eight separate cases of clinical diphtheria are recorded in table 1. Some presented a membrane in both the nose and the throat, and therefore the number of examinations reported under the heading "culture from lesion" is greater than the total number of cases. Throat cultures were taken in sixty-five cases and nose cultures in forty-one cases. Of the sixty-five throat cultures, sixty-four were positive by the rapid method. In these sixty-four cases with positive rapid cultures the results of the Loeffler cultures reported by the two laboratories were as follows:

- 1 In fifty-two, both laboratory reports were positive.
- 2 In nine, one laboratory report was positive, the others being negative.
- 3 In three, both laboratory reports were negative.

In no instance was the Loeffler method positive and the rapid method negative. One case of nasal diphtheria showed negative throat cultures by both methods. Similarly in cultures taken from the nose a larger number of positive results was obtained by the rapid method than by the Loeffler method in either one or both laboratories.

From the Willard Parker Hospital and the Department of Pediatrics, Cornell University Medical College.

- 2 Sole, Alphonse. Rapid Culture of Diphtheria Bacilli. *Wien Klin. Wchnschr.* 47: 713 (June 8) 1934.
- 3 Horse serum saturated with chloroform as a preservative may be used.

Since it is the culture from the membrane that is of greatest practical importance to the clinician, the last line in table 1 is of especial interest. There were seventy-four cultures taken from seventy-four different diphtheria membranes. All were positive by the rapid method. On the other hand, the two Loeffler slants, inoculated from each membrane, were reported positive in one or both laboratories seventy-one times. This

‡ Cases of tonsillar or pharyngeal diphtheria with negative nose cultures.

left three "double" Loeffler cultures, taken directly from the membrane, which were reported negative for diphtheria bacilli but which were positive by the rapid method.

Controls—The control group consisted of twenty-eight patients with membranous lesions in the throat due to various conditions such as streptococcal tonsillitis or pharyngitis, Vincent's angina and leukemia. Patients with an atypical membrane in the nose or throat are admitted to the hospital with the classification of "observation for diphtheria" because they do not present definite cases of diphtheria. If successive nose and throat cultures on Loeffler medium are negative for diphtheria bacilli, the diagnosis of streptococcal infection is made (if no other etiology for the membrane is found).

There were twenty-eight sets of throat cultures and fifteen sets of nose cultures taken in the control group. Most of the cultures were negative by both methods, as shown in table 2. Four patients with negative throat cultures on Loeffler medium but positive rapid cultures are of particular interest. The bacilli isolated from three of these four patients were virulent. We correlated the clinical data with our laboratory results. One of the three patients with virulent bacilli had a negative Schick test and was apparently a carrier with a non-diphtheritic membrane in the throat. Another patient received antitoxin at the time of admission when his temperature was 103 F. The temperature gradually subsided and was normal after five days. The third patient had exudate on her tonsillar tabs and a temperature of 103 F. Some of the examining physicians thought she had diphtheria and others did not. Cultures (Loeffler) from the Board of Health laboratory were negative and therefore the diagnosis of streptococcal infection was made. A Schick test examined at the end of twenty-four hours looked as if it might become positive and for that reason diphtheria antitoxin was administered. The patient's temperature was normal after three days. Did these two patients have diphtheria with negative Loeffler cultures? We are not certain that they had diphtheria but we do know

that the rapid cultures showed that they harbored virulent bacilli, a fact entirely missed in the Loeffler cultures.

COMMENT

The factor of greatest importance in the prognosis in diphtheria is how early in the disease antitoxin is administered. During the past decade the incidence of diphtheria has decreased, with the result that physicians are less "diphtheria minded" and less familiar with the appearance of the diphtheritic pseudomembrane. Perhaps for these reasons antitoxin is not administered in many cases of diphtheria until a positive report on a culture is obtained. At present culture reports necessitate a delay of at least eighteen hours and usually more than twenty-four hours. Although we do not advise waiting for the report of a culture before giving antitoxin in suspected cases of diphtheria, this dangerous waiting period is decreased to four hours by the rapid culture method. Furthermore, the rapid culture of diphtheria bacilli can be done by the practicing physician because no special incubator is necessary.⁴ We have found that the culture will be satisfactorily incubated by placing the test tube in the vest pocket for four hours. At the end of that time slide smear preparations can be made and stained with alkaline methylene blue or preferably Ponder's stain.⁵

DIPHTHERIA BACILLUS CARRIERS

The diphtheria bacillus carriers are an irksome problem in a contagious disease hospital. These perfectly well children and adults are confined to the hospital because in a routine nose and throat culture organisms resembling diphtheria bacilli were found.⁶ For both the hospital and the patient it is desirable to determine, as quickly as possible, whether diphtheria bacilli are present and if so, whether they are virulent. Only those harboring virulent diphtheria bacilli need be hospitalized. The usual cultures on Loeffler medium from a particular carrier will be positive on some days and negative on others. Whether this is because there are relatively few organisms present or for some other reason we do not know. In order to determine more accurately whether diphtheria bacilli were present and,

6. By a recent order of the Board of Health of New York City, presumptive diphtheria carriers are not hospitalized unless the bacilli which they harbor are shown to be virulent. (*Quart. Bull. City of New York Department of Health* 3:1, 1935).

Loeffler medium was emulsified and used immediately for an animal test for virulence. The intracutaneous test in guinea-pigs was employed as a routine.

RESULTS

The results obtained with the new rapid method are compared with the routine Loeffler cultures in table 3. Culture sets were taken in twenty-two carriers and the results tabulated separately for nose and throat cultures. To simplify the comparison of the old method with the new one the total number of cultures recorded in the last line of table 3 may be used. All cultures were positive twelve times. The transplant was positive and one Loeffler culture was negative ten times. Animal tests in these ten cases showed that the bacilli in nine of them were virulent. Even more striking were the fifteen culture sets that were negative on both Loeffler slants but positive on our transplants. Among the fifteen there were six with virulent bacilli as shown by animal inoculation. The new transplant method for

TABLE 3—Twenty Two Carriers Comparison of the New Transplant Method with the Old Loeffler Method (Loeffler Method Culture Examined in Two Laboratories)

Total cultures	12	10 (9 virulent)	15 (6 virulent)	2 (1 virulent)	5	

identifying carriers failed in one throat culture and one nose culture, which were reported positive on Loeffler medium by one of the laboratories.

COMMENT

In comparison with the methods used until now, our new method gave more uniform results in the morphologic identification of diphtheria bacilli. Although Jarema and Smith⁷ and others have shown that there is a relationship between the morphology of the diphtheria bacillus and its virulence, most laboratories still depend on animal tests in determining virulence. To obtain a culture pure enough for animal inoculation, the old methods require subcultures on agar plates, which are time consuming and as a result, a minimum of five days is necessary for a virulence test. By our rapid culture transplant method a growth pure enough for animal inoculation is obtained within twenty-four hours, thus saving from two to five days in performing a virulence test.

CONCLUSION

A rapid method for the morphologic identification of diphtheria bacilli is described and the work of Sole corroborated. The technic is simple and can be used by the practicing physician. The method is quicker and more accurate than that employing the Loeffler blood serum medium. A new more reliable method for the identification of diphtheria bacilli in suspected carriers is described in detail. This forms the basis for a more rapid technic for the virulence test in animals.

FROM PATHOLOGY TO EPIDEMIOLOGY IN TUBERCULOSIS

SOFTENING OF THE CASEOUS TUBERCLE AND ITS RESULTS

ESMOND R. LONG, MD

Director of the Laboratory of the Henry Phipps Institute for the Study Treatment and Prevention of Tuberculosis and Professor of Pathology University of Pennsylvania School of Medicine

PHILADELPHIA

The approach to epidemiology in current teaching is commonly by way of bacteriology. In diphtheria, scarlet fever, influenza, pneumonia, plague and infectious diseases in general, hygienists and sanitarians have concerned themselves chiefly with the etiologic agents of the diseases, the means by which they are spread and the measures that may be taken for prevention.

In tuberculosis epidemiologic stress has been laid on the tubercle bacillus, the sputum that acts as a vehicle in its dissemination, the closeness of contact between patients and healthy children or neighbors, and the methods by which the chain of infection from man to man may be broken, including isolation of the sputum-positive patient, the collapse of the infected lung to prevent the outflow of infected sputum and, at times and in some places, attempts at immunization of the patient's children.

In their clear perception of the means by which this chain may be cut, physicians have generally overlooked the phenomenon that starts the chain in the first place. This phenomenon, which puts pathology and epidemiology on common ground, is softening of the caseous tubercle. It is on this phenomenon that clinical medicine also, in treatment of the individual patient, should focus more of its attention than is at present the case.

The problem of softening of the caseous tubercle may justly be considered the key problem in tuberculosis. If caseous tubercles did not soften the disease would be self limited and would die out with the end of the present cases, except for occasional cases dependent on unusual methods of transmission. The simplicity of facts concerned may readily be seen in the following brief summary of the course and spread of progressive pulmonary tuberculosis. The lung is infected by tubercle bacilli; cellular and subsequently caseous tubercles are formed, and some of these soften. The softened caseous matter is discharged into the bronchioles and aspirated into other parts of the lung, with the production of new tubercles, some of which in turn soften, or it is coughed into the outside world, where other people may be infected. That is, in short, the whole story.

The specific character of softening of the caseous tubercle has not been sufficiently emphasized. In textbooks on general pathology the two phenomena of caseation and softening are commonly not separated, and the distinctive nature of the latter process is not stressed in spite of the fact that the first adequate description of the morbid anatomy of tuberculosis gave clear expression of the distinction. In the *Médecine auscultatoire* of Laënnec¹ the course of tuberculosis is divided into stages of infiltration, crude tubercle and softening. Laënnec wrote:

In whatsoever manner these crude tubercles [i. e., caseous tubercles] may be formed, they finish by becoming

Read before the Olmsted-Houston-Fillmore-Dodge-County Medical Society at the Mayo Clinic, Rochester, Minn., Nov. 22, 1934.

softened and liquefied. When the tuberculous matter has completely softened, it breaks its way into the nearest bronchial tube. The resulting aperture being narrower than the cavity with which it communicates, both remain fistulous even after complete evacuation of the tuberculous matter

Fig 1—A section of lungs of I F, aged 74, who had tuberculosis for forty years and who was presumably responsible for the familial spread shown in B. B, chart of family of I F showing active tuberculosis in I F and presence of first infection and latent reinfection tuberculosis in members of his household. For further explanation see the text.

But if the phenomenon of softening of the tubercle has been underemphasized in the pathogenesis of tuberculosis, even less attention has been directed to a collateral event that gives the process of softening both its pathologic and its epidemiologic importance. Associated with the softening, an extraordinary multiplication of tubercle bacilli occurs. At the stage when the product of tuberculous infiltration first discharges into a bronchus, it has maximum infective power. Not before, nor again after, are tubercle bacilli to be found, in the region concerned, in the concentration coincident with softening.

This fact also has long been known. In the Etiology of Tuberculosis,² which bears the same classic relation to the bacteriology of tuberculosis as the Mediate

auscultation to its pathology and clinical care, Robert Koch wrote

The bacilli are present in greatest number in fresh caseous infiltrations and the interior of cavities the walls of which are undergoing rapid liquefaction. They are encountered less numerous in cavities with indurated walls and are least frequent in scarred, contracted, pigmented lung tissue.

Indeed, the soft yellow lumps sought by the technician examining sputum, in order to save time in finding tubercle bacilli, are nothing more than bits of debris from the liquefying caseous nodules. Their presence in sputum is proof of softening with fresh excavation, and they are as good indexes of progressive disease as the elastic fibers described at length in all textbooks of clinical pathology.

The extraordinary abundance of tubercle bacilli in freshly softening caseous tubercles, if not generally appreciated, is, nevertheless, well known to specialists in the pathology of tuberculosis. In his comprehensive monograph on the Pathologic Anatomy of Tuberculosis, Huebschmann³ emphasized the fact that, whenever liquefaction processes are developing, quantities of tubercle bacilli are easily recognizable, adding that he had never seen progressive liquefaction begin without some bacilli. In his well known studies on the early lesions of reinfection, Assmann⁴ was impressed by the huge numbers of bacilli to be found in these lesions at the time of beginning excavation. Yet the facts are not current teaching, and new direction of attention to their existence seems timely.

In illustration of the double phenomenon of softening and abundance of tubercle bacilli, three cases will be cited from the experience of the Henry Phipps Institute, as representative of three types of case. The

Fig 2—A, low power view (hematoxylin and eosin stain) of wall of large cavity in lung of I F (left apex fig 1 A). B, high power view of inner margin of same (upper margin of A stained for acid fast bacteria). Only one or two tubercle bacilli are visible.

three patients concerned were an elderly Jew with pulmonary tuberculosis of exceptional chronicity, a young American white adult with fatal pulmonary tuberculosis

2 Koch Robert. Die Aetiologie der Tuberkulose. Mitt. d. Kaiserl. Gesundheitsamts, Berlin 2. 1884.

3 Huebschmann Paul. Pathologische Anatomie der Tuberkulose. Berlin Julius Springer 1928.

4 Assmann H. Fruhinfiltrat. Ergebn. d. ges. Tuberk. 1. 145. 1930.

of ordinary duration and a Negro child with "adult type" tuberculosis of extraordinary severity and rapid progression. The phenomena of softening and bacillary multiplication were qualitatively the same in all three but varied quantitatively with the type. The three cases cited may be considered to represent the two extremes and the average in the intensity of the processes concerned.

Fig 3—A low power view (hematoxylin and eosin stain) of softening nodule in lung of I F. B high power view of the same (central region of A stained for acid fast bacteria). Large number of tubercle bacilli present.

REPORT OF CASES

CASE 1—I F, a Jew, aged 74 married and the father of six children, five living and one dead, entered the clinic of the Henry Phipps Institute Jan 5, 1933 stating with pride that he had never had a doctor in his life. He admitted, on questioning, that he had had a 'dry cigaret cough for forty years.' He came to the clinic because for the past four months he had suffered with more severe cough with expectoration and from dyspnea and exceptional fatigue. On physical and roentgen examination he was found to have far advanced bilateral pulmonary tuberculosis. The sputum was positive for tubercle bacilli with a Gaffky count of 5. He was sent to the Philadelphia General Hospital where he died June 1 1933. Post-mortem examination showed bilateral fibroplastic and ulcerative pulmonary tuberculosis, with disseminated chronic bronchogenic tuberculosis throughout all lobes, with numerous spots of softening and early cavity formation in the bronchogenic tubercles. Almost no normal tissue remained (fig 1A). A large calcified tubercle was found in the base of the left upper lobe and a small calcified tubercle in a left hilus lymph node.

The wife and three children were examined in the clinic of the Phipps Institute. One child had died at the age of 6 years of an unknown cause. Two children said to be well had left the family and could not be examined. The wife, aged 50 and the other children one aged 21 years and a pair of twins aged 23 all had large healed primary infections readily visible by x rays and definite evidence of latent apical tuberculosis of the reinfection type.

The life lines for I F the wife and the children are shown as routinely drawn in the Phipps Institute family charts in figure 1B. In view of the almost total involvement of the lungs, it is probable that the 'cigaret cough' which had lasted for forty years was really due to tuberculosis and I F's line is marked

with solid dots (presumptive tuberculosis) accordingly. The solid blocks at the bottom of the line, extending to the right and left of the line, indicate clinical tuberculosis and positive sputum respectively. On the lines of the wife and children the solid circles, the solid circles within circles, and the triangles attached to segments of circles represent respectively nodules of first infection, calcified tracheobronchial nodes, and latent apical tuberculosis of adult type.

In this case the tuberculosis of the children is probably to be attributed to long contact with the father, since the lesions were diagnosed as of long standing (McPhedran) and since experience in the Phipps Institute indicates that universal infection of the children of a family is usually the result of intrafamilial spread. As to the tuberculosis of the wife, little can be said, as she was about 25 years old when she married. However the experience of the institute indicates that conjugal superinfections are common when one partner has positive sputum.⁵

The character of the exposure to which the family was subjected is indicated by figures 2 and 3. Bacilli were readily demonstrable in the cavity walls and the areas of softening and were much more numerous in the latter than in the former. It may reasonably be assumed that the sputum at all times contained moderate numbers of bacilli from the walls of the old cavities (fig 2) and that they were present in much larger numbers intermittently whenever caseous bronchogenic nodules

Fig 4—Section from lung of A S. Note spot of softening and drainage into bronchiole in upper right quadrant.

softened and discharged their contents (fig 3). On all occasions corresponding with the last named event the chances for infecting others by cough must have been exceptionally great. In most of the regions of softening, tubercle bacilli were from ten to twenty times as

⁵ Opie, E. L. and McPhedran, F. M. Exogenous Tuberculous Infection of Adults. Arch. Int. Med. 50:945 (Dec.) 1932.

numerous as in the walls of old cavities. They were, however, in general much less numerous than in corresponding areas of softening in cases 2 and 3. This fact is to be correlated with the much greater chronicity of the disease in case 1. I F represented the well known type of Jew with extreme chronicity of tuberculosis. The wife and children, subject to heavy infection with tuberculosis present but inactive, may be considered as of the same relatively resistant type.

CASE 2—A S, a white man aged 29 married, the father of one child, admitted to the clinic of the Henry Phipps Institute Oct 28 1933 complained of cough, expectoration and weakness. On physical and roentgen examination he was found to have far advanced bilateral pulmonary tuberculosis with tuberculous laryngitis. He was sent to the Philadelphia General Hospital where he died December 14. At postmortem examination far advanced ulcerative tuberculosis of each upper lobe was found, with extensive bilateral chronic bronchogenic nodular tuberculosis, with numerous foci of softening (fig 4), regions of caseous bronchopneumonia, and tuberculous bronchitis and tracheitis.

Fig 5—A, low power view (hematoxylin and eosin stain) of wall of a large cavity in lung of A S (not pictured in figure 4). B, high power view of inner necrotic margin of same (upper margin of A stained for acid fast bacteria). Few tubercle bacilli are present (note small group on upper margin).

His wife, aged 26, was not tuberculous on roentgen examination. A tuberculin test was not done. The 2 year old child reacted intensely to tuberculin (four plus; i. e., reaction with superficial necrosis, to 0.01 mg of old tuberculin) and was found by roentgen examination to have a tuberculous nodule in the lower lobe of the right lung and several enlarged lymph nodes in the right hilus, some of them partly calcified.

In figures 5 and 6 some indication is given of the exposure to which those surrounding A S were subjected. As in case 1, tubercle bacilli were present both in the necrotic debris lining the walls of old cavities and in the semiliquid matter of softening caseous nodules or newly forming cavities. They were, however, literally hundreds of times as numerous in the latter as in the former location, the growth was essentially like that on artificial culture mediums. The section illustrated in figure 6 comes from the area seen in the upper right quadrant in figure 4. As shown in figure 4, this soft area has been partly excavated. The region communicates as the illustration shows, with a

bronchiole, and since it was partly excavated it may be assumed that, shortly before the death of A S, discharge of semiliquid matter containing enormous numbers of tubercle bacilli had taken place in this bronchiole. Other similar regions were in the neighborhood, some in a more and some in a less advanced stage of softening and excavation. It is not surprising that the child of 2 years, living in the household of this patient, was heavily infected. Again, as in case 1, it may be assumed that, intermittently, corresponding with periods of discharge from such softening nodules, as shown in figure 4, A S was more dangerous than ordinarily to those around him. The bacilli were growing in his softening nodules on a greater scale than in case 1, and the much shorter life of A S may be related to this fact.

CASE 3—C D, a Negro boy, aged 8 years was referred by his school to Clinic No 3 of the Philadelphia Health Council because he had been coughing violently and persistently in class for some weeks past. Physical and roentgen examination, March 8 1933 showed far advanced bilateral pulmonary tuberculosis of the adult type. The sputum contained tubercle bacilli (Gaffky 4 by count). The boy was sent to the Philadelphia General Hospital where he died September 24. At postmortem examination extensive ulcerative and caseous tuberculosis with massive areas of softening was found in the upper two thirds of each lung. A retrogressing tuberculous primary complex was found in the left lung. There was a recent generalized tuberculosis in addition.

The source of infection was not determined with certainty, although it was probably the landlady of the house, who lived with the family, who was emaciated and had a chronic persistent cough and who frequently took care of the boy in the absence of the parents. The parents appeared to be well, but they and the landlady refused to be examined for tuberculosis.

On the basis of figure 7, one may speculate on the infection for which C D, in turn must have been responsible. The lungs contained many foci, like that represented in figure 7, with tremendous numbers of tubercle bacilli growing in colonies as in culture mediums. In microscopic sections stained for tubercle bacilli the colonies were so large as to be easily visible to the naked eye. According to his teacher's statement, he had been coughing in class for weeks. Countless tubercle bacilli must have been sprayed around the room in that time. Had it been possible to tuberculin test the children of his classroom, probably an exceptionally high incidence of reactors would have been found. Hetherington, McPhedran, Landis and Opie⁶ have reported instances in which pupils have apparently widely infected their comrades in the classroom. Such infection does not commonly occur in the lower grades of grammar school, because ordinarily children in the preteen ages do not have ulcerative pulmonary tuberculosis. Occasionally, however, tuberculosis of this character does occur in children, and more commonly in Negro than in white children, as in case 3. Such cases are responsible for some proportion of the positive tuberculin reactions in children when no contact with tuberculosis is present within the family.

COMPARISON OF CASES

These three cases illustrate the same phenomenon—the presence of enormous numbers of tubercle bacilli in caseous lesions undergoing softening. In all cases the number of bacilli was much greater in the softening lesions than in the walls of old cavities. The latter, which are commonly considered the chief source of

6 Hetherington H W, McPhedran F M, Landis H R, Opie E L. A Survey to Determine the Prevalence of Tuberculosis Infection in School Children. *Am. Rev. Tuberc.* 20: 421 (Oct.) 1929.

spread of bacilli represent a late stage in the process of excavation and the residua of acute excavations which at their height contained huge numbers of bacilli but long previously discharged their contents

The three cases represent fairly well three groups that may be distinguished as respects severity and rapidity of progression of pulmonary tuberculosis

Fig 6—A low power view (hematoxylin and eosin stain) of softening region in lung of A S (the softened region in upper right quadrant in figure 4). B high power view of same (central region of A stained for acid fast bacteria) showing a huge number of bacilli

These are (1) very chronic cases lasting from twenty to fifty years, traditionally common in Jews, as was the fact in case 1 of this series, but by no means confined to this race nor constant in it, (2) cases of a few years' duration, commonly less than three, seen typically as average examples of "consumption" in white adults, as in case 2, and (3) cases of rapid progression, lasting only a few months as far as can be determined clinically seen typically in this country in Negroes, and in especially severe degree in Negro children, as in case 3. The numbers of bacilli found in the softening lesions, when averaged for several regions in each type, are found to be in direct proportion to the severity of the type, being most numerous in the type of case illustrated in case 3. Corresponding numbers of bacilli may be expected in the sputum. Direct evidence that such is the case is seen in the work of Opie and Isaacs⁷ and of Hughes,⁸ who found by a long series of Gaffky counts that the average number of tubercle bacilli in the sputum from progressive pulmonary tuberculosis is much greater in Negro than in white patients. The chances for infection in the neighborhood of Negro patients are therefore presumably greater

THE NATURE OF THE PHENOMENON

Neither the cause of the softening of caseous nodules nor the explanation of the enormous number of tubercle bacilli present is definitely known. It is commonly taught that softening is due to the proteolytic action of

leukocytes, present as a result of secondary bacterial invaders or as a direct response to the tubercle bacilli themselves. But softening occurs quite as commonly in the absence of leukocytes as in their presence. In the cases here illustrated (figs 3, 6 and 7) leukocytes were not particularly numerous in the softening regions. The phenomenon is not equivalent to suppuration.

Occasionally bacteria and fungi, not chemotactic for leukocytes but possibly rich in proteolytic enzymes, are present. This was true in case 2 of this series, but softening is common when such microbic forms are not present and when nothing can be distinguished microscopically but disintegrating caseous matter and tubercle bacilli.

It has frequently been suggested that softening is an allergic process comparable to the Koch phenomenon, representing a reaction between tubercle bacilli, with their content of tuberculin, and highly hypersensitive tissue. Huebschmann⁹ considered softening "the most intense reaction of hypersensitiveness to be encountered in the human body." He felt that clinical correlation with it might be detected. Pagel⁹ presented experimental evidence for the allergic nature of the phenomenon. Jaffe¹⁰ recently stated with regard to the infraclavicular infiltrations that these much discussed lesions, "with their massive exudation and quick liquefaction, carry the earmarks of an allergic inflammation." There are however, several objections to the view that all softening of this character is on an allergic basis. The chief of these is the fact that the allergic state, as far as it can be measured by the tuberculin skin reaction is commonly of low degree in late stages of the disease when softening and resultant excavation are at their height. In case 3 which illustrated the highest

Fig 7—A low power view (stained for acid fast bacteria) of softening region in lung of C D. B, high power view of same (from upper quarter of A same stain) showing a huge number of bacilli

degree of softening and multiplication of bacilli in the cases here recorded, the tuberculin reaction was only one plus to 0.01 mg of old tuberculin six months before death. Commonly the reaction is negative shortly

before death. It may be, however, that some other type of sensitization than typical tuberculin allergy is concerned, as has recently been suggested by Lurie.

Lurie¹¹ has shown that the phenomenon of softening and multiplication of bacilli is in every way comparable in experimental tuberculosis to that seen in human cases. He has found repeatedly that coincident with the softening of tubercles in rabbits a huge increase in the number of bacilli can be demonstrated both by comparative counts of bacilli present in unsoftened and softened lesions and by plating out equivalent weights of the two types of tissue and counting the colonies cultured.

It is not yet clear whether this tremendous growth of tubercle bacilli precedes or follows the softening. If the former, the nutritional factors permitting the multiplication are hard to understand, in this case, however, the large number of bacilli present might well be the cause of the softening. If subsequent research proves that the softening comes first the multiplication of bacilli can be explained on the basis of the new opportunity afforded by the softening for oxygen ingress and flow of fluids containing nutritive elements.

CLINICAL ASPECTS OF PHENOMENON OF SOFTENING

It is questionable whether softening lesions can be recognized clinically. Exacerbations of cough may have this origin, but obviously there is nothing constant about cough at any time. The areas are as a rule multiple and too small (fig. 4) to yield distinctive physical signs. Roentgenograms do not distinguish unsoftened and softening caseous nodules until the latter progress to small cavities. Softening may be suspected only by inference from the general course of the case. It is of constant occurrence in rapidly progressive cases.

Yet it is a matter of vital concern in the treatment of tuberculosis. The disease spreads, inside of the lung and in the outside world largely because of the vast numbers of tubercle bacilli in the softened areas. The ideal treatment, for the sake of the patient and of those around him, is one that will prevent this spread. The only method of absolute prevention would be obstruction of the outlet. Tuberculous regions, unlike abscesses due to pyogenic bacteria, do not tend to "point" and so may be imprisoned with safety. Localization approaching that from complete obstruction may result from mere nonmovement of the lung, for in a motionless lung no active force is in play that will lead to discharge of the softened contents. The retention of this highly infective material is not as dangerous as might be supposed. Investigations in this laboratory indicate that such lesions, if they cannot drain commonly become encapsulated, and the huge numbers of bacilli tend to die off, presumably for want of nutriment and oxygen.

Relaxation of the lung, with kinking of the soft-walled bronchioles into which softened regions drain, "kinking of the type stressed as favorable by Coryllos," will also tend to prevent escape of the highly infective contents. Either effect may be the result of proper pneumothorax. Improper pneumothorax, which in this case would be pneumothorax with positive pressure, might well result in expulsion of the semiliquid,

bacillus-rich mass and aspiration into healthy parts of the lungs.

In any event, in the treatment of pulmonary tuberculosis by lung collapse, the matter of freshly softening caseous nodules should be kept in mind. In general clinical practice the collapse of cavities has been used as a gage of the success of pneumothorax, and the change of the patient from the sputum-positive to the sputum-negative state is commonly credited to the cavity collapse. As a matter of fact, this change must be attributed to the retention of the soft matter of small liquefying tubercles as much as or more than to the obliteration of cavities, the walls of which are ordinarily poor in bacilli as compared with the zones of fresh softening. Therefore in the procedure of lung collapse and search for improvement in its technic, the pathologic process of softening of caseous nodules should be considered of first importance.

SUMMARY

1 Tuberculosis in its epidemiologic aspects has its source in a specific pathologic phenomenon, softening of the caseous tubercle.

2 The phenomenon of softening of the tubercle has long been recognized but not commonly identified as a specific pathologic process, distinct from caseation.

3 The significance of softening of the caseous tubercle for epidemiology lies in the fact that associated with it is an enormous multiplication of tubercle bacilli. The latter are commonly hundreds or thousands of times as numerous in the semiliquid contents of softening caseous nodules as in the necrotic walls of old cavities.

4 Three types of case (illustrated by reports in this article) may be distinguished in a general way on the basis of the number of bacilli in the softening regions, a chronic type with a moderate concentration of bacilli in the softening lesions, an intermediate type, and an acute type with vast numbers of bacilli.

5 The fundamental nature of the process of softening is still unknown. It is not equivalent to suppuration. Attempts to put it on an allergic basis have not been entirely successful.

6 The softening tubercle should receive more clinical consideration than is at present the case. Successful treatment of tuberculosis by lung collapse owes its favorable outcome as much to prevention of drainage of liquefying tubercles as to the obliteration of large cavities. Lung collapse, improperly applied, particularly with excessive pressure, even when obvious cavities are obliterated, may result unfavorably through expulsion of highly infective liquefying matter into tributary bronchioles. The most appropriate lung collapse, as far as the softening tubercle is concerned, is that which stops motion of the lung and partially or completely obliterates the small bronchiolar outlets from the liquefying masses.

Origin of the Name Protein—In 1838 the Dutch chemist Mulder separated and described such a material and believing it to be the fundamental constituent of tissues, he gave it the name protein, derived from the Greek verb meaning "to take the first place." While Mulder's chemical work did not prove to be of great permanent value, the word which he coined has lived and is used essentially as he intended, except that now we know so many such substances that the term usually takes the plural form—Sherman, H. BLOOD VESSEL TUMOR OF THE
SPINAL CORD IN A BOY
AGED NINE YEARSWITH SPECIAL REFERENCE TO A NEW
DIAGNOSTIC SYNDROME

WILLIAM C. BLACK, MD

AND

HAROLD K. FABER, MD

SAN FRANCISCO

Blood vessel tumors and varices of the spinal cord are rare. Globus and Doshay¹ in their comprehensive review of the subject in 1929 were able to collect only fifty-eight cases from the literature, which include three distinct pathologic entities. There have been reports of five new cases since that time making a total of sixty-three cases. Of the total number, about 10 per cent were purely arterial or presented an arterial component. The remaining 90 per cent were composed of about equal numbers of true neoplastic hemangiomas and of venous dilatations, the latter are not neoplastic formations but have been included in all reviews of the subject, presumably because of the similarity of the clinical syndrome. Guillain² reports one other instance in which both conditions were found. In most cases the lesion has not been fully exposed at operation and the suspicion may be entertained that in at least some

REPORT OF CASE

E. S., an American schoolboy, aged 9, admitted to Stanford University Hospital, Jan 17, 1934, complained of pain in the lower part of the back of fourteen months' duration. Adenotonsillectomy had been performed shortly before, during an acute attack of tonsillitis. After the operation he was very ill with a high fever. Four days later he began to have lumbar pain, which persisted till the time of admission. When he began to walk, about the fifth day after the adenotonsillectomy, his legs were weak and he walked 'bent over like a little old man'. The weakness of the legs became gradually worse and finally, about a month before entering the hospital, he became completely bedridden. His illness was punctuated by periods of severe sciatic pain and by attacks of muscle cramps, which would double him up into grotesque postures for hours or days at a time. He lost a great deal of weight. There was some dribbling of urine and one attack of complete retention during the two or three months before admission.

On physical examination there was a marked generalized emaciation, most apparent in the legs. The lower part of the spine was fixed in a smooth kyphosis and there was tenderness to jarring over the lower three lumbar spines. The erector spinae muscles and those of the buttocks and posterior part of the thighs were extremely atrophied and were practically powerless. The knee jerks were absent. The achilles jerks were hyperactive, with a poorly sustained clonus on the right. The Babinski sign on both sides was positive. The abdominal reflexes were absent except in the left upper quadrant. The cremasteric reflexes were absent. Temperature and deep pain sensations were diminished in the legs up to the groin, but there was no sharp sensory level. Position and touch sensations were intact.

of the cases described as simple vascular dilatations a true neoplasm has also been present. Only one case of blood vascular cord tumor has been reported, prior to the present one, in an individual under 10 years of age.⁶ The illustration of the lesion in Cobb's report shows a mass of dilated veins such as was found at the first laminectomy in our case.

LABORATORY REPORTS

Roentgenograms of the spine showed no bone disease but did reveal kyphosis and scoliosis.

Examination of the blood showed hemoglobin 80 per cent, erythrocytes 5,000,000, leukocytes, 7,700, polymorphonuclear neutrophils 50 per cent, lymphocytes 41 per cent. The urine was normal. The tuberculin test was positive (1,200 intracutaneous). The blood Wassermann reaction was negative. The sedimentation rate was 8 mm in one hour. There was no reaction of degeneration.

On lumbar puncture the fluid was markedly xanthochromic and coagulated spontaneously, with a pressure of 20 cm. The Queckenstedt test was definitely and repeatedly negative on several trials. Pressure over the jugular veins caused the fluid to rise promptly in the manometer, and when the jugular pres-

sure was removed the fluid level fell promptly to the original level. After 5 cc of spinal fluid was withdrawn, however, the pressure fell to zero, the Queckenstedt test became positive and no more fluid could be obtained. Straining and jugular pressure would produce only a few drops more and then air went back into the needle showing it still to be in place.

On cisternal puncture 0.75 cc of descending iodized poppy-seed oil was injected. Roentgenograms showed a curious distribution of the oil in droplets of varying size from the eighth to the tenth thoracic vertebra (fig 1).

January 25 a laminectomy was performed by Dr E B Towne. The arches of the ninth, tenth and eleventh thoracic

Fig 1—Roentgen appearance of 0.75 cc of descending iodized poppyseed oil seen in anteroposterior projection, distributed from the eighth to the tenth thoracic vertebra.

vertebrae were removed. The dura pulsated in the upper two thirds of the field. The dura was opened, the arachnoid being left intact. Through the latter could be plainly seen a tangled mass of large veins, from 0.5 to 2 mm in diameter over and around the cord. The bulk of the cord seemed to be increased. In the upper and lower fourths of the operative field a considerable area of spinal cord could be seen between the enlarged and tortuous veins. Droplets of iodized oil could be seen collected around

and between the coil of veins in the upper part. No arterial component was found. The dura was left open and the wound closed.

For a while after the operation the patient did well. He was given 800 roentgens of high voltage therapy in four days. On the eighth postoperative day he could stand. The knee jerks returned and the ankle clonus disappeared. The degree of sensory loss diminished. The Babinski sign remained positive on both sides. Within a month he was able to walk from twenty to thirty steps unassisted. Then occurred the first of his setbacks, of which he has had four to date, consisting of sudden increase in the muscular weakness of the legs, occurring every month or two with gradual improvement between, each exacerbation being more severe than the last. After the fourth of these exacerbations on physical examination the lower extremities showed a complete flaccid paralysis, except for slight motion at the hip on the right and a little more motion at the hip on the left. All deep reflexes in both legs were absent. Atrophy of the muscles was more marked than before. The ankles were swollen. Touch, pain and temperature sensations were somewhat diminished up to the groin, but there was no definite sensory level. The position sense remained intact. Another lumbar puncture was performed. The changes were identical with those encountered four and a half months before. The From syndrome was present and Queckenstedt's sign was negative, becoming positive after the removal of 5 cc of fluid. The pressure on this occasion was 25 cm, 0.5 cc. of descending iodized poppy-seed oil was injected into the lumbar sac and roentgenograms, after inversion of the patient, showed the lower border of the lesion to be at the level of the second lumbar vertebra, three segments below the lower border of the previous operation.

Dr Towne performed a second laminectomy, June 23. The arches of the twelfth thoracic and the first, second and third lumbar vertebrae were removed and the lesion was found to extend to the lower border of the second lumbar vertebra, where it appeared to end. The notable differences between the appearance of the lesion on this occasion and that seen previously were that there was definite erosion from pressure

of the laminae of the second lumbar vertebra and the tumor pressed out the dura more than before—so much so that it was with some apprehension that the dura was opened over it. When this was done a picture quite different from that seen at the previous operation was revealed. There was a large red, homogeneous tumor, no varices were seen. It seemed certain that this was a hemangio endothelioma. It did not seem safe to excise a piece for microscopic examination.

The boy was given another course of high voltage roentgen therapy. At the present time two months later he is slightly better than he was before the second operation.

Cases of the sort under consideration have proved difficult to diagnose prior to operation. Globus and Doshay¹ undertook their study with the professed hope that analysis of the cases would provide some means of making clinical diagnosis possible but concluded that there are no specific diagnostic features. Sargent⁴ first emphasized the characteristic variability of symptoms and physical signs from time to time during the clinical course of the disease. In only two instances has an angioma of the overlying skin segment given a clue to the spinal cord lesion.⁵ Referring to the value of special procedures Globus and Doshay¹ state that laboratory, manometric and iodized oil tests have not been carried out systematically and hence offer no data which would permit of an analysis. The accompanying table shows the changes in each of the seventeen cases that have been so studied.

In only four of the sixteen cases, all reported by Globus and Doshay,¹ were the results of spinal puncture entirely normal (cases 5, 7, 8 and 11). It is worthy of note in view of the observations made in our case that the Queckenstedt sign was positive only once (case 13), an instance in which the lesion occupied nearly the entire subarachnoid space from one end of the cord to the other. Further, in two cases (7 and 13) out of eight in which iodized oil had been injected a distribution of the droplets similar to that in our case has been present, and in one of the remaining cases (12) "partial obstruction" was present. In two others (cases 14 and 15) there was a complete block to iodized oil. In case 3 there was

Fig 2—Lateral view

anthochromia without any evidence of block to iodized oil, which Bucy⁶ suggests is probably due to transudation of serum and blood pigments, which discolors the spinal fluid above as well as below the tumor. He reports a case in which anthochromia without obstruction was found above a blood vascular tumor and led an unwary surgeon into operating at the wrong level.

ECZEMA VACCINATUM—ELLIS

1891

ECZEMA VACCINATUM ITS RELATION TO GENERALIZED VACCINIA

REPORT OF TWO CASES

FRANCIS A ELLIS M.D.
BALTIMORE

Reports of cases of eczema vaccinatum in the American literature are relatively few, and the fact that this disease and generalized vaccinia are basically the same is not generally accepted.

The vaccine virus used today is a smallpox virus that has been attenuated by many passages through calves, and Schamberg and Kolmer¹ state that this attenuation is permanent and irreversible even by innumerable transfers. The virus in a case of variola is definitely disseminated by the blood stream but that the vaccine virus is also disseminated in this manner is not universally recognized.

Gins and his co-workers² demonstrated that the virus in an uncomplicated case of vaccinia was present in the throat on the third and fourth days after vaccination and then disappeared even before the take developed. They also showed that the virus could be found at about this time in the internal organs such as the liver, spleen and brain. Paschen³ gave a full discussion of the observations of the various investigators on the proof of whether the vaccine virus enters the general circulation after cutaneous inoculation. He concluded that in many cases, if not in all, the virus is disseminated by the blood stream sometime after vaccination.

Fig. 1 (case 1).—Appearance September 15 (biopsy taken the same day) on about the fifth day of the eruption showing the extensiveness of the lesions and their tendency to become confluent.

CUTANEOUS REACTIONS DUE TO THE VIRUS

In this article only those skin eruptions will be considered which are directly due to the virus itself and in which the etiologic agent can be proved by performing Paul's test⁴ (inoculation of the virus on a rabbit's cornea) on the suspected lesion.

The importance of these fortuitous eruptions was shown by Blockmann's⁵ review of the literature from 1880 to 1904. His eczematous son developed an eczema vaccinatum accidentally from an older vaccinated

It is apparent that our case presents a unique combination of spinal fluid changes. The conjunction of the From syndrome with a negative Queckenstedt test, which becomes positive when the lumbar sac is drained of a relatively small amount of fluid, could probably not be produced by any type of lesion other than the one under consideration. The vascular tumor, whether composed of varices or smaller vessels transmits pressure from the subarachnoid space above to the lumbar sac below thus acting essentially as a column of liquid even though there is no direct communication between the two. However, when the fluid is drawn off below and the tumor sags down under the unopposed pressure from above the attachments of the tumor are drawn tight, producing an obstruction in the spinal canal like that of a solid tumor and so causing the Queckenstedt test to become positive.

Worthy of special attention is the peculiar distribution of iodized oil in droplets over two or more segments present in the case here described and in two others (cases 4 and 13). The combination of such a distribution of iodized oil, a From syndrome and a Queckenstedt test changing from negative to positive after the removal of spinal fluid below the lesion affords a characteristic and probably pathognomonic picture of subarachnoid varices and vascular tumors large enough to cause obstruction.

The progress of the case here reported harmonizes with the pessimistic view expressed by Sargent⁴ and Rand⁵ that operation is of little or no permanent value. Globus and Doshay¹ believe that operation affords some benefit as the result of decompression. Our patient was slightly unproved after operation but only for a short time. Spontaneous remissions, especially in cases of varices, have been repeatedly noted and may explain temporary improvement as well as does decompression. High voltage roentgen therapy was without detectable effect.

SUMMARY

In a case of intradural venous blood vascular tumor, probably hemangio-endothelioma with associated varices, in a boy aged 9 years, the combination noted of the From syndrome, a negative Queckenstedt test becoming positive after withdrawal of spinal fluid below the lesion, and a peculiar distribution of iodized oil in droplets suggests that it may be pathognomonic of subarachnoid varices and vascular tumors of the cord large enough to obstruct the subarachnoid space. Clay and Webster streets.

The Limitations of Mental Testing—All sorts of tests have been devised for all sorts of purposes particularly the best known is the test of intelligence which, as it is now used, is used in the form of the Stanford modification of the Binet-Simon. This test has now been in use for many years and yet if we tried to find out what this intelligence is that we are testing we would find that no one knows. Intelligence up to the present time is undefinable. It is so complex and so intricate that it eludes any effort to compress it into a single formula. This has finally become obvious to the people who are engaged in this work themselves and so instead of speaking of intelligence they speak of test intelligence which is equivalent to saying in response to the question 'What is this intelligence that you test?' It is that which is tested by the intelligence tests. Nevertheless again we discover that by using these tests we have unearthed an enormous amount of information.—White W. A. The General Implication of Psychiatric Thought third of the Thomas W. Salmon Memorial Lectures read before the New York Academy of Medicine April 26 1935

brother Lesions developed mostly on the eczematous areas but also on the right cornea, which caused blindness in the affected eye Blockmann collected 135 cases of vaccinia with fortuitous lesions, twenty of which were in eczematous children, six of which were fatal Forty-six of the 135 cases presented ophthalmic lesions, but the exact extent of this complication was not usually stated, although some did result in blindness Of the 135 patients, only twenty had definitely never been vaccinated Accidental vaccinia is relatively common and its danger depends primarily on the site Nehen pocken is the development of vaccinia lesions in the region about the site of the take This type of reaction is seen only occasionally, and is due to local spread of the virus by scratching or by way of the lymph spaces It is practically harmless, only increasing the amount of scarring necessary for a successful take

Generalized vaccinia is considered as that type of reaction to vaccination in which lesions develop on the normal skin on distant parts of the body These lesions may occur concurrently with the original inocu-

Fig 2 (case 1)—Discrete and fusing vesiculopustules on the arm and chest. Note the opalescent elevated and umbilicated lesions characteristic of vaccinia

lation or a few days later If later, the lesions tend to become more and more atypical or of an abortive type All authors on this subject agree that the virus is disseminated by the blood stream when this complication occurs The frequency of generalized vaccinia lesions in vaccination cases is estimated by Danziger⁶ in 900,000 cases as one in about every 30,000 cases and by Anders⁷ on the basis of 3,000,000 vaccinations as one in 40,000 Marick⁸ reported a case in the American literature, which occurred in a girl, aged 3 years, who had a severe primary take, as this began to involute, successive crops of generalized pustules appeared on the normal skin, accompanied by mild general symptoms and fever This condition persisted for four weeks Froumy's⁹ experiences with generalized vaccinia are unique and frequently cited He revaccinated 175 cadets with the same vaccine, fifty-five had no reactions, but twelve had generalized

eruptions, four of which were severe and one was fatal Cases of generalized vaccinia have also been reported by Haslund,¹⁰ Swoboda,¹¹ Althoff,¹² Korach,¹³ Groth,¹⁴ Chalke,¹⁵ Pautrier,¹⁶ Anders⁷ and Shortt¹⁷ Anders' and Shortt's cases were fatal, and Haslund's patient had been vaccinated successfully many years before

Eczema vaccinatum is essentially a generalized vaccinia occurring in a patient who has a skin eruption, usually an eczema It may occur in secondary syphilis (Danziger), impetigo and the like and is thought by most authors to be due to auto-inoculation of the virus from the operative wound to the diseased areas

Templeton's¹⁸ case was very unusual Unknown to him, his patient was vaccinated two days before he removed about ten moles from her face and neck A primary type of reaction developed in the vaccinated area and in the desiccated lesions Templeton did not state whether the wounds were dressed or if an anti-septic was applied

In 1882 Martin¹⁹ reported a case of eczema vaccinatum in a 7 months old eczematous boy, who, Martin thought, was inoculated by way of the intestinal tract after being nursed by the infant's recently vaccinated mother Contact between the eczematous child and another brother, who was vaccinated at the same time as the mother, was disclaimed Recently Platou²⁰ reported a fatal case in an eczematous infant An excellent illustration accompanies the article

Cases of this type have been reported by Sprengel,²¹ Werther,²² Jessner,²³ Finkelstein,²⁴ Steiner,²⁵ Eichhoff,²⁶ Lortat-Jacob,²⁷ Kobrak,²⁸ Kritiz,²⁹ Geronne,³⁰ Gate,³¹ Esquer and Germain,³² Uffenheimer,³³ Hegler,³⁴ Haslund,¹⁰ and Kaiser and Blass,³⁵ making a total

of twenty-two cases. The age varied from several months to 42 years, and five of the cases were fatal. Paul's test was made in two cases and both were positive.

Danziger⁶ reported the occurrence of six cases within a period of eleven days with a vaccine that gave many normal takes. Most of the inoculations were accidental and one was fatal. He also mentioned ten other cases which he had previously seen, and he stated that the disseminated lesions were due to auto-inoculation. Busch³⁶ cited a case in an eczematous boy who had two attacks within a period of four years. The second eruption was fatal and lesions occurred even in the scars caused by the first attack.

REPORT OF CASES³⁷

CASE 1—Stanley S., aged 3, was one of twins, both of whom had eczema. The eczema first appeared on Stanley when he was 19 months old and was of the severe infantile type occurring mostly on the face and arms with a tendency to moderate remissions and marked exacerbations. He was first admitted to the University Hospital in October 1931 because of marked eczema of the face and scalp and to a less extent over the rest of the body. Much secondary infection was present and two positive blood cultures were obtained which showed *Staphylococcus haemolyticus*. The rectal temperature varied from 100 to about 104 F, and the leukocyte count averaged 15,000 with 20 per cent eosinophils. While in the hospital he contracted mumps and was discharged soon afterward, March 1, 1932, unimproved. He was readmitted March 25, 1932, to be put on a milk-free diet but whooping cough developed and he was again discharged. At this time his leukocyte count varied between 15,000 and 20,000 with 6 per cent eosinophils.

Fig. 3 (case 1)—Section under low power of a lesion in the vesiculopustular stage with marked destruction of the epidermis. Note the dense polymorphous infiltrate in the rete and subepidermal layers. Figure 4 is a high power view of the area marked 4.

The patient was admitted to the Bon Secours Hospital July 14 and was discharged September 2. Here his improvement was moderate and the clinical course was negative, except for occasional peaks of fever up to 103 F. About the first of September his older brother Joseph was vaccinated in preparation for entering school and a large take developed about 4 by 5 cm in diameter. September 12, Stanley was readmitted to the University Hospital because many discrete pustules had

appeared about the face and later on the rest of the body. The pustules were round or oval about 1 cm in diameter, raised, pearly white or opalescent, and rapidly became umbilicated, later fusing and finally covering the face with a thick purulent crust. The child was very toxic, with marked abdominal distention and a fever that varied between 103 and 104 F. On the morning of the seventeenth, the possibility of variola was suggested and the patient was taken to an isolation hospital, where he died the next day.

A biopsy was performed September 15, from two fusing lesions on the abdomen that were beginning to become delled

Fig. 4 (case 1)—Section under high power. The intracellular edema and the pathognomonic intracellular extranuclear Guarnieri inclusion bodies (denoted by the arrows) are clearly shown.

Under low power there was a partially destroyed hair follicle separating the two lesions which were in a vesiculopustular stage. The infiltrate and debris were greatest in the region of umbilication. There was a thin layer of stratum corneum present over the entire lesion, but in many areas most of the epidermal tissues were destroyed, leaving only occasional islands of squamous cells which were apparently parts of hair follicles. About the border of the lesion the interpapillary pegs were elongated and broadened, and the cells themselves were paler and larger than usual, with some in various stages of balloon degeneration. Under high power, occasional mitotic figures were seen, while in other areas definite inclusion (Guarnieri) bodies could be demonstrated. Below the thin stratum corneum in the area of vesiculation which contained besides serum fibrin and leukocytes were partially destroyed cells of various sorts and debris. These elements were increased in the deeper tissues giving the entire vesicle a broad base made up of polymorphonuclear cells in various stages of degeneration and nuclear fragments. These changes extended into the middle of the corium. Bacterial stains showed groups of organisms just below the surface of the lesion.

CASE 2—The other twin, William, in the course of investigating contacts was found to have many lesions on the face and body, especially about the upper left eyelid, axillae, arms, scapulae and knees. These lesions were of the same type as on Stanley, whitish, opalescent papules of from 0.75 to 1 cm in diameter which as they enlarged became umbilicated. He also had a few larger crusted lesions, especially on the abdomen. The child was vaccinated at this time but it did not take.

When William was seen in June 1934, a chronic dry excoriated eczema was still present about the flexor surfaces of the arms, and several oval, 1 cm sized nonpitted, depigmented scars were present about the axillae and knees.

The diagnosis of eczema vaccinatum was finally made for the following reasons: 1. The eczematous child who died was home just at the time when his older brother was developing a severe primary reaction due

36. Busch, N. Ueber Eczema vaccinatum. Arch. f. Dermat. u. Syph. 107: 471, 1933.

37. Private cases of Dr. H. M. Robinson and reported with his permission.

to vaccination 2 The clinical course, the primary lesions and the microscopic appearance substantiated that diagnosis 3 William the twin brother, who also had eczema, developed an eczema vaccinatum at this time which healed with slight scarring and subsequently his vaccination did not take 4 Many unvaccinated infants were exposed while Stanley was in the University Hospital but they did not develop variola

It is regrettable that Paul's test was not made or that Paschen bodies were not looked for in the fresh lesions

DIFFERENTIAL DIAGNOSIS

In the diagnosis, besides variola Kaposi's varicelliform eruptions and Juliusberg's³⁸ pustulosis varioliformis or vacciniiformis acuta must be considered Only variola and vaccinia will give a positive Paul test

Concerning the term Kaposi's varicelliform eruptions it should be understood that even up to 1900 varicella was considered a mild form of variola These cases, as exemplified by Brown's³⁹ and McLachlan's⁴⁰ recent reports, usually occur in eczematous patients, and these cases cannot be differentiated from eczema vaccinatum on clinical grounds The same applies to the disease described by Juliusberg³⁸ in 1898 as pustulosis acuta vacciniiformis Juliusberg in his original report mentioned that his case was similar to Kaposi's varicelliform eruptions Recently similar cases have been reported by Feit,⁴¹ Baar,⁴² and Freund.⁴³ The latter author attempted a Paul test on the suspected lesions, but a severe keratitis developed It is questionable whether Kaposi's varicelliform eruption and Juliusberg's disease will prove to be variants of some other cutaneous disease or definite entities

Freund,⁴⁴ early in 1934, expressed the same opinion when he reported a case under the ambiguous title of "pustulosis vacciniiformis acuta" (Kaposi-Juliusberg) and definitely proved the case to be eczema vaccinatum by causing a keratoconjunctivitis in a rabbit On microscopic examination the cornea showed numerous inclusion bodies, although apparently grossly just a severe nonspecific keratitis was present He suggested that the clinical picture in eczema vaccinatum may vary as the virulence of the vaccine virus and that of the secondary bacterial invader

COMMENT

The vaccine virus is a modified variola virus and the latter is definitely spread through the body by the blood stream, attacking specifically the epidermal tissue It has been stressed again and again that areas which have been traumatized, even only by pressure, tend to be attacked more than other areas That the vaccine virus is disseminated at times by the blood stream causing generalized vaccinia is not disputed

The fact that in eczema vaccinatum the lesions appear mostly or only in the eczematous areas does not prove that the virus arrives there by autoinoculation because, as with smallpox, the virus may be prone to develop in an area of lowered resistance Certainly the extensiveness of many of these eruptions, their occurrence

also at times in noneczematous areas and the involvement of internal organs such as the liver, spleen and meninges, all point to clinical evidence of blood stream dissemination of the virus

The fact that Paul,⁴⁵ by the use of a protective bandage to the operative area in an eczematous patient, prevented (?) the development of an eczema vaccinatum really proves nothing There is no inkling in the literature of the number of patients with skin eruptions such as eczema and impetigo who do not develop a generalized vaccinia after vaccination⁴⁶

CONCLUSIONS

1 In a review of the literature on generalized eruptions due directly to the vaccine virus, only a few cases were found in the American literature To these are added the two cases presented

2 From the literature and the evidence from the cases presented it is thought that eczema vaccinatum and generalized vaccinia are essentially the same and that in both diseases the virus is disseminated by the blood stream

3 Eczema vaccinatum is apparently at times diagnosed Kaposi's varicelliform eruption or Juliusberg's pustulosis vacciniiformis or varioliformis acuta

Clinical Notes, Suggestions and New Instruments

DUODENORENAL FISTULA

GEORGE C. BIONDI, M.D., NEW YORK

A fistulous communication between the duodenum and the pelvis of the right kidney though described only casually even in the more elaborate treatises on urology, constitutes an extremely rare clinical entity That its potentiality has been recognized since time immemorial is indicated by the fact that even Hippocrates makes mention of it in his *Opera Omnia*, yet in all these centuries I have found but three cases recorded in the entire medical literature

The earliest report is that of Rayer,¹ in which he describes the case of Dr. Campaignac A tailoress, aged 45, was admitted to the hospital, Jan. 10, 1835, and died March 6 of the same year without operation The duodenorenal communication was discovered at autopsy Turner² reports the case of a youth aged 18, admitted to St. George's Hospital with severe hematuria and advanced tuberculous disease of the lungs At autopsy the right kidney was found to be scrofulous and its pelvis communicated with an abscess cavity situated in front of the organ and in contact with the colon and duodenum There were several ulcerated openings in the second portion of the duodenum by which the bowel communicated with the abscess There are several reports of fistulous communications between the large bowel and the kidney, typical of which is the case of d'Allaines and Rouffiac,³ in which an opening between the colon and the left kidney existed Recently Davis⁴ reported an interesting case of ureteroduodenal fistula which he was able to demonstrate by urography

45 Paul G. Studie über die Aetologie und Pathogenese der sogenannten generalisierten Vaccine bei Individuen mit vorher gesunder oder kranker Haut. *Arch. f. Dermat. u. Syph.* 52:3 1900

46 Dr. J. C. G. Ledingham, director of the Lister Institute of London in a personal communication states that the virus in vaccination is always generalized that it tends to localize in areas of lowered resistance that the guarmer bodies are pathognomonic of either vaccinia or variola, and that the inoculations for diagnostic purposes are made preferably in the rabbit's skin rather than in the cornea

Since careful search of the medical literature in this country reveals no record of any occurrence of true duodenorenal fistula, the following case is reported

S W, a white woman, aged 28 born in Germany a hair dresser, applied for treatment at the urologic clinic of St John's Hospital, Long Island City, N Y, April 12 1933 Her symptoms for the past nine months had been those of marked dyspepsia with frequent vomiting soon after eating and paroxysms of severe, lancinating pain in the right flank radiating anteriorly below the costal margin and down toward the groin These attacks came on often at night without ingestion of food lasted from one half to three hours, and generally assumed such an intensity that the patient was compelled to remain at home for two months She managed to return to work, but early in December she had to be taken home during another seizure and from then until admission to the hospital she spent most of her time in bed There was no frequency of urination until about one month prior to hospitalization, when it increased to about eight times a day and once at night with some dysuria The appetite was poor and vomiting was easily instigated by the ingestion of meat condiments or sweets The weight was 116 pounds (52.6 Kg) the patient having lost only 11 pounds

Fig 1—The opaque fluid instilled by the retrograde method has extravasated from the right renal pelvis into the duodenum

(5 Kg) since the beginning of her illness The blood pressure was 120 systolic 68 diastolic the temperature was 101.8 F

Physical examination revealed the scar of an appendectomy performed five years previously the questionable presence of a mass in the right upper quadrant tenderness somewhat below the right costal margin, and exquisite rebound tenderness on hammer percussion over the right costolumbar angle

April 19, 15 cc of a 20 per cent solution of skiodan was introduced into the right renal pelvis and 7 cc into the left one through 5 F shadowgraph catheters

Figure 1 shows the dye to have extravasated from the right renal pelvis into the duodenum

Against our advice the patient deferred entering the hospital until May 3

The clinical examinations showed repeated catheter specimens of urine to contain usually 2 plus albumin sometimes acid at other times alkaline and the pus on microscopy would vary from 10 cells per low power field to a heavy sediment The blood counts showed a variation in leukocytes from 12,000 to 22,000 in erythrocytes from 3,170,000 to 4,200,000 in hemoglobin from 59 to 80 per cent in polymorphonuclears from 73 to 87 per cent Chemical examination of the blood revealed

a urea nitrogen of only 10.3 mg creatinine 1.22 mg and sugar 877 mg per hundred cubic centimeters The blood Wassermann reaction was negative

On cystoscopy, May 8, about 1½ ounces of purulent milky-looking, foul urine was recovered from the bladder On inspection the sphincter was congested, the 'bas-fond' showed large

Fig 2—The opaque fluid instilled into the right renal pelvis has traversed a considerable portion of the small intestine.

Fig 3—Fistulous communication through which the dye and the shadowgraph catheter have entered the duodenum

patches of mucus adhering to the mucosa which was considerably injected Both ureteral ostia were visualized in their normal location and both catheters were advanced easily for 28 cm The urinary drip was so slow that after forty-five minutes only about 3 cc was obtained from either side, that from the right being milky and foul The patient seemed to be dehydrated on account of attacks of vomiting

Figure 2 taken after the instillation of 125 per cent solution of sodium iodide in both renal pelvis shows the opaque fluid to have traversed a considerable portion of the small intestine. Another ureteral catheterization, on May 12, was performed for the purpose of obtaining more definite information regarding the function of the left kidney, and it is worthy of mention here that the patient seemed to feel much relief for a day or two after each cystoscopy. The drip from the left renal pelvis at this time was much more satisfactory, but none came from the right, though 5 cc of a creamy looking fluid was obtained on suction.

Phenolsulphonphthalein, 1 cc intravenously, appeared in three and one-half minutes from the left side only and the specimen collected for the next ten minutes showed a 12 per cent color concentration.

Laboratory Report May 12

	Right	Left
Pus	Heavy sediment	5 leukocytes per high power field
Urea	Sufficient specimen	2.64 Cm per thousand cubic centimeters
Tubercle bacilli	Smear negative	Smear negative
Culture	Gram positive cocci Large and small gram negative bacilli Occasional gram positive bacillus Nonhemolytic streptococci	No growth in 48 hours

May 19, through a shadowgraph catheter advanced high up into the right ureter, 1 ounce (30 cc) of 25 per cent sodium iodide was injected into the renal pelvis and exposures were taken at fifteen minute intervals. While the last portion of the dye was being instilled rather rapidly, the patient experienced a salty taste in the mouth accompanied by nausea and a gush of projectile vomiting, but no pain.

Figure 3 demonstrates most accurately the point of union between the two structures, the shadowgraph catheter having entered the lumen of the intestine through the renal pelvis.

Fig. 4—Pyelographic study of the right kidney the day before discharge from the hospital.

At the completion of the last exposure, 5 cc of indigo carmine solution was injected through the catheter, but it evidently underwent decomposition, the result of the enema the following morning showing only a coffee brown fluid containing the same color stool. A gastro-intestinal series also was done but the results were only prolapse of the transverse colon and periduodenal adhesions. Operation was performed, May 26 by the transperitoneal route. A difficult and painstaking

dissection demonstrated a perfectly fitting anastomosis, about one-half inch in diameter, the descending portion of the duodenum being united with the pelvis of the right kidney. After the repair of the intestine was completed it was thought advisable to remove what appeared to be a hopelessly hardened and enlarged kidney, but in the manipulation of freeing it from the peritoneal adhesions a large abscess broke open from its posterior surface and the field of operation was literally bathed in thick, greenish pus. Drainage was quickly established ante-

Fig. 5—The iodized poppy seed oil injected into the sinus in the right flank has entered the abscess in the kidney.

riorly and posteriorly, and the abdomen was closed in layers. Convalescence was very stormy and in the course of the next five weeks intravenous therapy had to be constantly administered and supplemented by blood transfusions. July 19 the day before discharge from the hospital, the pyelogram (fig. 4) to check up the condition of the right kidney revealed a dilatation of the pelvis with blunted and misshapen calices. Phenolsulphonphthalein appeared in four and one-half minutes on this side but the color concentration was only 7 per cent in fifteen minutes.

Weekly inspection in the outpatient department was carried out because of slight but persistent drainage from a sinus of the posterior incision which did not close until the latter part of February 1934. The general condition was then excellent; she weighed 135 pounds (61.2 Kg). The patient felt well until June 20, at which time she experienced a sudden throbbing pain in the right flank with tumefaction, chills and fever. A large abscess broke open spontaneously on the examining table and she was again admitted to the hospital.

Catheterization of the right ureter at this time showed only a faint trace of phenolsulphonphthalein after twenty-five minutes; roentgen examination revealed a very small kidney outline and an intrarenal abscess was demonstrated by injecting iodized poppy seed oil through the sinus in the flank (fig. 5).

Nephrectomy yielded a kidney the size of a small lemon, the actual weight being only 40 Gm, although at the previous operation it had appeared to be close to 40 ounces (1,134 Gm). There was no appreciable pulsation of the vascular pedicle; there was only a vestige of the fatty capsule, and the few adhesions encountered were not at all troublesome. The pathologic diagnosis was tuberculosis of the kidney.

COMMENT

A thought in retrospect of this unusual case comes, of necessity, to every one's mind. Was a perforating duodenal

ulcer the initial factor in the *modus operandi* or was there a preexisting kidney lesion which, by way of a perirenal abscess, became attached to and finally ulcerated into the duodenum? In proportion, renal lesions certainly occur with overwhelmingly greater frequency. In 17,652 postmortem examinations at Guy's Hospital there were only seventy cases in which an ulcer of the duodenum, either open or healed was discovered.⁵ Yet all the authors who refer to this condition agree to the two way possibility and the majority state that the initial focus of infection is usually of the tuberculous type.

I believe that the ulcerative process originated in the duodenum, because the gastro-intestinal complaint preceded the urinary disturbance by several months because of the repeated failure to encounter any obstruction of the right renal tract, and because of lack of evidence of tuberculous changes on pyelography.

125 East Fifty-Fifth Street

IDIOSYNCRASY TO HEXYLRESORCINOL

CARL W. WALTER, M.D. BOSTON

The unusual severity of the manifestation of an acquired sensitivity to hexylresorcinol warrants the report of this case. Idiosyncrasy to hexylresorcinol has been described by Templeton and Lunsford¹ and by Cummer.²

Fig 1—Second degree burn caused by contact with hexylresorcinol

REPORT OF CASE

History.—An American woman aged 57, a housewife scratched the dorsum of her left hand on a jagged piece of glass protruding from the frame of a broken window. A wet

dressing of hexylresorcinol solution was applied for approximately thirty minutes, and the injury was dismissed as trivial. Twenty-four hours later the area moistened by the dressing began to itch and burn, and the skin about the scratch became red and swollen. Vesicles formed in the center of the lesion during the following day. As the lesion spread, the vesicles coalesced to form large blebs. Itching and burning sensations were supplanted by a dull throbbing ache. Three days following the original injury the patient sought medical advice at the outdoor department of the Peter Bent Brigham Hospital.

The family history showed that there was asthma in the mother, brother and nephew.

The patient had had five pregnancies, one complicated by phlegmasia alba dolens. Two daughters have hay fever, one having rheumatic heart disease as well. In another hive develops following the ingestion of lobster or strawberries, a phenomenon first noted during an attack of chorea.

Strawberries and tomatoes cause hives in the patient. Recurrent ulcers of the left leg were treated with numerous salves for twelve years. During the period from May to October 1931, moist dressings of hexylresorcinol solution were applied to the ulcers in conjunction with pressure bandages. The ulcers healed temporarily. Following this the patient could recall no contact with hexylresorcinol until the present illness.

Examination.—The patient was obese and well preserved and had a ruddy complexion. The general physical examination was unremarkable except for a blood pressure of 180 systolic, 130 diastolic, with slight cardiac enlargement and the usual evidence of postphlebotic ulcer over the lower left leg.

A vesicular and bullous eruption surrounded by an elevated, erythematous, sharply demarcated border covered the dorsum of the left hand and wrist. The purplish red bullae contained a serosanguineous viscid fluid. There was no increased warmth, and tenderness could not be elicited. Motions of the hand and arm were painless. No lymphadenopathy was noted. The extent and characteristics of the lesion are illustrated in figure 1.

Course.—On the first visit to the clinic a small area over the solar aspect of the right arm was scarified lightly and fresh hexylresorcinol solution was poured over the area. An erythematous wheal appeared within a period of one hour and the area began to sting. Intense burning and itching preceded vesicle formation. In twenty four hours the lesion appeared as illustrated in figure 2.

Treatment consisted of bland washes during the first forty-eight hours. Then, because of the extension of the original lesion and the development of headache, lassitude, feverishness (temperature 99.5 F) and thirst the areas were thoroughly tanned with tannic acid and ointment (5 per cent). The systemic reaction ceased promptly. When the eschar was removed after ten days, complete healing had occurred.

Fig 2—Skin test twenty four hours after application of hexylresorcinol to scarified area.

² Cummer C. L. Dermatitis from the Use of Hexylresorcinol Solution. S. T. 37. Acquired Sensitivity. J. A. M. A. 100: 884 (March 25) 1933.

Laboratory studies showed that the urine was normal and the Wassermann reaction negative, culture from blebs taken on the third day yielded *Staphylococcus aureus*.

On a follow-up examination eight months later the skin of the hand appeared normal. A second skin test was applied resulting in erythema and vesicle formation in twelve hours.

SUMMARY

Cutaneous sensitivity to hexylresorcinol was acquired by external application of the drug over a period of five months. Twenty-six months later, severe dermatitis resulted from a single brief contact with the drug.

URETERAL STRICTURE AND HYDRONEPHROSIS AS LATE SEQUEL OF KIDNEY INJURY

DANIEL N. EISENDRATH, M.D., PARIS, FRANCE

In cases of kidney injury in which recovery has occurred after nonoperative treatment one is apt to overlook the late effects of such an injury to the kidney and the corresponding ureter. Only a few articles have thus far appeared which show the value of intravenous (excretory) and of ascending (retrograde) pyelography in the determination of how much damage has been done in these cases.

The importance of the subject from the standpoint of industrial and ordinary accident insurance cannot be overestimated. In all cases thus far reported the interval between the time of injury and that of the examination has been a relatively short one, hence the report of a case in which the accident occurred twenty years before the reappearance of symptoms referable to the injured kidney may be of interest.

A man, aged 39 while traveling in Europe had a sudden symptomless hematuria. When I first saw him at the American Hospital, Paris he stated that the hematuria had first been noticed three days before. The onset had been sudden, without any prodromal symptoms. The urine had remained uniformly bloody during these three days without any pain or other symptoms that could aid in localizing the source of the hematuria. He stated that he had fallen on a slippery sidewalk twenty years before and immediately noticed pain over

the patient had no symptoms referable to the injured kidney until the sudden onset of the hematuria for which he came to the hospital twenty years later.

Examination of the urinary tract, Dec 1, 1934, revealed the following: Urine passed before the introduction of the cystoscope contained a large amount of blood (grade 4) intimately mixed with the urine. Intravenous (excretory) pyelography revealed a normal renal pelvis and calices on the right, but a complete absence of any shadow on the left side (fig 1) at the end of fifteen minutes. Plain radiography failed to show any abnormal shadows due to calculi. On cystoscopy the bladder urine was found to contain a large amount of blood. Aside from marked hyperemia of the walls and the trigon the bladder examination failed to reveal anything abnormal. The left ureteral orifice was edematous, but the right one was normal in appearance. Urine obtained by ureteral catheterization from the right kidney was normal on examination and in diligo carmine given intravenously appeared in four minutes on the right side, showing an apparently good function of the corresponding kidney. The urine obtained by ureteral catheterization from the left side was as bloody as that in the bladder. Ascending (retrograde) ureteropyelography on the left side showed a moderately advanced degree of hydronephrosis in the shape of a large, obliquely placed shadow (fig 2) in the left kidney region. Where this shadow passed over into that of the ureter there was a sudden interruption or filling defect about 1 cm in length in which one could see only a faint shadow, indicating a narrowed passage between the renal pelvis and the ureter. The latter from this level down to the bladder showed a wider shadow than normal, but this was interpreted as being due to the fact that the opaque medium employed for the ascending pyelography had encountered a resistance at the upper end of the ureter with a resultant artificial widening of the ureteral shadow.

Fig 2—Results of ascending (retrograde) ureteropyelography on the left side. Note the large diffuse shadow in the kidney region indicating the hydronephrosis. Between this large shadow and the ureter there is an almost complete filling defect, indicating the seat of traumatic stricture of the ureter.

Fig 1—Results of intravenous pyelography at end of fifteen minutes. Note the absence of any excretion on the left (injured) side and the presence of shadows of the normal pelvis and calices on the right side.

the left kidney region. The first urine passed after the accident contained considerable blood. Both the pain and the hematuria continued for two weeks but gradually decreased until the urine, on macroscopic examination became clear. Since that time microscopic examination of the urine has revealed at intervals, the presence of red blood cells. At the time of the accident, twenty years before, cystoscopy and ureteral catheterization showed that the source of the hematuria was the left kidney. The injury was treated conservatively and

My interpretation of these changes is that at the time of the injury twenty years before the ureter had been almost completely torn across at its junction with the renal pelvis. The result of this ureteral injury had been the formation of a stricture sufficiently patent however to allow some of the opaque medium, injected from below to pass through and fill the dilated renal pelvis. The patient was kept under observation for five days. The severe hematuria continued during this period and was at times accompanied by the passage of clots. Nephrectomy was advised on account of the constantly increasing anemia but the patient refused any operative intervention and returned to New York.

The case is reported because it shows in the first place that an injury of the ureter may be followed by as serious a sequel as injury of the kidney itself and secondly that it may serve

to direct attention to the necessity of keeping a patient who has sustained a severe reno-utereral injury under surveillance for a much longer period than one has been accustomed to deem necessary. Bleeding from a hydronephrosis is not at all uncommon, and this best explains the severity and persistence of the bleeding. In all probability, the gradual decrease in the lumen of the ureter, at its point of origin from the renal pelvis, explains the slow development of the hydronephrosis and the consequent absence of symptoms during the interval of twenty years from the time of injury.

The case is important from the standpoint of indemnity, both industrial and ordinary (nonindustrial).

About two months after examination of the patient a letter was received from Dr. Paul W. Aschner of New York stating that he had removed the left kidney. The specimen showed an S-trap ureteropelvic obstruction and an enormous hydronephrosis. Dr. Aschner was of the opinion that the obstruction was of congenital origin and that it had been present at the time of the original injury twenty years before and that it had predisposed the patient to the hemorrhage following the injury.

GLANDULAR PHYSIOLOGY AND THERAPY

CORPUS LUTEUM THERAPY

GEORGE W. CORNER, M.D.
ROCHESTER, N. Y.

NOTE.—These articles and the articles in the previous issues of THE JOURNAL are part of a series published under the auspices of the Council on Pharmacy and Chemistry. Other articles will appear in succeeding issues. When completed the series will be published in book form.—Ed

The title of this article, "corpus luteum therapy," of course indicates scarcely more than a hope for the future, I am sadly aware that its perusal cannot immediately result in curative benefit to a single patient. Nevertheless it will be profitable to consider the subject as it stands today, from the mutual standpoint of the practitioner and the investigator. Such consideration will not only explain the physiologic basis on which practical applications are to be worked out but also help, it is hoped, to clear away the misconceptions and false hopes by reason of which in the past so many bottles and pill boxes have been filled with elegant but inert pharmaceuticals.

FUNCTION OF THE CORPUS LUTEUM

Speaking broadly, the endocrine function of the corpus luteum is now well understood, the gland is a part of the mechanism of pregnancy, and its general action is exerted on the uterus to put that organ into a proper state for the reception and nutriment of the embryo. When an ovum begins its journey through the fallopian tube, the follicle wherein it took origin gives place to the corpus luteum, and this organ thereupon begins to deliver into the blood stream a substance that has the property of causing extensive development of the uterine glands so that the histologic structure of the endometrium is greatly altered.

By the time the fertilized ovum reaches the uterus the endometrium is therefore already in a state of

heightened secretory activity, by which presumably nutritive substances are provided for the embryo, moreover, it is in some way sensitized so that it responds to the presence of the embryo by forming the maternal part of the placenta and the decidua. Experiments on animals have amply shown that removal of the corpus luteum during the earlier part of pregnancy causes failure of implantation of the embryo, or, if the embryo is already implanted, it causes destruction of the pregnancy.

So far as is known at present, the corpus luteum has no useful action except in pregnancy, but in most mammals, including the human species the gland is formed in every cycle, in anticipation (so to speak) of pregnancy, and therefore in each human cycle the corpus luteum normally acts for about two weeks, giving rise to the so-called premenstrual stages of the endometrium. Thus in the adult nonpregnant human female the corpus luteum is functioning about half the time, but in animals with less frequent cycles the proportion of corpus luteum function is much less, the nonpregnant bitch, for example, gets along in perfect health without corpora lutea for about ten months of the year. Obviously, therefore the corpus luteum is not necessary for general well being.

PROGESTIN

The hormone of the corpus luteum, which gives the effects described, has been extracted from the ovaries of swine and has been named "progesterin" (i. e., favoring gestation) by myself and my colleague Willard Allen. The name "corporin" has been applied by Hisaw and his collaborators to the same hormone as it occurs in their extracts. Investigations by Butenandt¹ and by Allen and Wintersteiner² reveal that progesterin is a crystalline hydrocarbon of formula $C_{27}H_{48}O_2$, melting at 128 C., having both oxygen molecules in ketone linkage. Beyond this point its chemistry is at the time of writing unknown. A recent statement by Slotta, Ruschig and Fels,³ that besides such a substance a second compound is necessary to produce the full effect, is not in agreement with the results of Allen and Wintersteiner.

Progesterin is administered subcutaneously, usually in solution in a vegetable oil, it cannot be given by mouth, because either it is not absorbed from the gastrointestinal tract or it is inactivated by the processes of digestion.

In castrated rabbits, progesterin readily produces pregnancy changes in the uterus, in rabbits castrated during early pregnancy, it will protect the embryos against the loss of their mother's corpora lutea and will maintain the pregnancy to full term. In guinea-pigs it sensitizes the uterus to produce the maternal placenta (Loeb's deciduoma).

Hisaw, Meyer and Fevold,⁴ Smith and Engle⁵ and I have severally succeeded in producing in monkeys the

premenstrual endometrium with progestin, and Kaufmann⁶ and a number of other European gynecologists have produced premenstrual endometrium in castrated women by administering large doses of estrogenic substance to bring the uterus back to its normal interval stage, and then progestin to effect the premenstrual changes.

The standard assay of progestin is performed by administering it for five days to an adult rabbit that has been mated and then castrated. A rabbit unit (Corner and Allen⁷) is the minimum quantity which, divided into five equal daily doses, produces on the sixth day a state of the uterus equal to that of the eighth day of a normal pregnancy. This unit is generally used in the American laboratories but in Germany a number of workers are using the Clauberg unit,⁸ which is measured in the same way except that miniature rabbits of 600 Gm weight are used, being primed with ten doses of estrogenic substance preceding the five days course of progestin. This Clauberg unit is apparently somewhat smaller than the American unit.

Action on Uterine Muscle—Besides the progestational effect on the uterine mucosa, extracts containing progestin also produce certain effects on the uterine muscle. Thus Reynolds⁹ has injected such extracts into rabbits in which he can study the spontaneous uterine contractions through a uterine fistula and finds that the drug renders the uterus temporarily quiescent. Knaus,¹⁰ who uses the excised rabbit's uterus in vitro, finds that corpus luteum extracts inhibit the normal response of the uterine muscle to the oxytocic principle of posterior pituitary. It is not yet certain whether such inhibition of uterine smooth muscle is due to progestin itself or to another hormone, the weight of published evidence favors the latter but experiments now in progress in my laboratory suggest reservation of judgment on this point. These reactions are not all the same in various animal species that have been tried, but there is evidence¹⁰ that the nonpregnant human uterus fails to respond to oxytocic principle of posterior pituitary during the latter half of the interval when the corpus luteum is present.

RELAXIN

Hisaw¹¹ has described another substance found in extracts of the corpus luteum, called relaxin, which is totally distinct from progestin and which has the property of relaxing the symphysis pubis in the guinea-pig in a manner similar to the normal relaxation which occurs in that species during pregnancy. The existence of relaxin as a specific hormone has not yet been inde-

pendently confirmed, but the details of the question need not detain us here, since no clinical considerations are as yet involved.

AVAILABILITY OF PROGESTIN

Returning to progestin, it must be said first that the expense and difficulty of preparation will greatly retard clinical trial, which will probably have to wait until the chemists discover how to synthesize the drug. In the United States, progestin has scarcely passed beyond the laboratories in which it was discovered. The experimental divisions of two or three of the large drug houses have prepared small quantities of the crude extract for trial and are experimenting with commercial purification, but as yet no preparation for clinical use has been put on the market. Several European manufacturers are, however, actually advertising the drug under various names, i. e. Proluton (Schering and Kahlbaum), Luteogan (Henning), Lutex (Leo).¹² These preparations are assayed in rabbit units and certainly contain the hormone as indicated by the fact that they were successful in the tests on human patients already mentioned.

CLINICAL POSSIBILITIES

Here then is a definite hormone, about to be handed to the medical profession to take the place of the meaningless corpus luteum preparations of the past. It has the property of bringing about premenstrual changes and the uterine conditions of early pregnancy. What is to be done with it? A few clues from the experimental side may be useful to the clinical investigators who must answer the question.

1 If there are, among the cases of sterility and of habitual abortion any which are specifically due to uterine disturbances caused by deficiency of the corpus luteum, progestin will help them, for it maintains pregnancy in castrated pregnant animals. Perhaps the drug will be useful in classifying such cases by therapeutic test. There is a report in the German literature of two cases of threatened abortion treated with supposedly favorable results.¹³

If, as many people still think, the corpus luteum has the property of inhibiting ovulation, it would be distinctly contraindicated in sterility of ovarian origin. The animal experiments on this point are however, not yet decisive.

2 With regard to the treatment of disorders of menstruation, the trouble is that there is simply not enough information about the part played by the corpus luteum in the menstrual cycle. At present it is difficult to believe that the corpus is primarily connected with menstrual rhythm. A discussion of the question will be found in a recent paper.¹⁴ If progestin has any effect, it is probably as a suppresser of menstruation. Any use of the hormone to affect the cycle will necessarily be in the nature of an experiment.

3 The German gynecologists who have had small amounts of progestin-containing preparations for clinical use have been interested in their action on metro-

rhagia and menorrhagia Kaufmann and Bickel¹⁵ report partially favorable results, including clinical cures of glandular hypoplasia with bleeding, and Knab¹² has had good results in two cases of "juvenile uterine hemorrhage" and six cases of "ovarian bleeding without pathologic observations." Presumably the theory underlying this work is that an agent which is able to cause growth changes in the endometrium may thereby improve the condition of a deteriorated bleeding mucosa, or perhaps the favorable result in some of these cases, if genuine, may come from the known power of progestin to antagonize estrogenic substance in some of its actions. Progestin might be useful, therefore in menorrhagia when (if ever) it is due to overaction of estrogenic substance. In these matters it will be best for the clinicians to go ahead with cautious trials for the time being, leaving the explanation to be worked out in the laboratory.

Attempted Indirect Therapy—In view of the present difficulty of getting authentic corpus luteum extracts for clinical trial, it has been proposed¹⁶ that corpus luteum therapy be achieved by treating the patient with the so-called anterior pituitary-like luteinizing factor of the urine of pregnancy. To this end preparations known on the market as "follutein" and "antuitrin-S" made from human pregnancy urine have been used. These extracts are highly potent in producing corpora lutea in rats and it was hoped that they would also luteinize the human ovary and thus give the patient a self-made supply of corpus luteum hormone, but evidence is totally lacking that the human ovary can be so luteinized. Monkey ovaries certainly cannot be so affected. If favorable therapeutic results follow the use of pregnancy urine extracts the relief of symptoms can therefore scarcely be considered to be due to the corpus luteum.

EMPIRICAL PREPARATIONS

Corpus luteum preparations of current American manufacture all date from the time before the physiology of the corpus luteum was well known, and they were all put into use on the basis of a vague hope that an organ obviously related to pregnancy and the menstrual cycle might somehow do good if given to patients with various reproductive disorders. None of them are assayed for progestin and so far as is known none of them contain it in effective amounts, because the methods of preparation or of administration are mostly such as to remove or destroy the hormone, if any of them contain any useful substance it is something unknown to science. Their use is therefore quite empirical and it may safely be predicted that they will become obsolete as fast as genuine assayed hormone-containing products become available.

In brief, the American practitioner now has at his disposal no corpus luteum therapy that has passed the test of experiment but current work with progestin promises to give in the future a corpus luteum hormone with which the possibilities of therapy may be explored.

MENSTRUATION

EDGAR ALLEN, PH D

NEW HAVEN, CONN

Recently the process of menstruation has been observed microscopically in the living animal by Markee.¹ This was accomplished by transplanting small pieces of endometrium into the anterior chamber of the eye, where they became vascularized and could be observed frequently for considerable periods. A graphic description of the onset and course of menstruation helps to vivify impressions of this hemorrhagic process as drawn from previous descriptions of histologic specimens.²

OBSERVATIONS ON THE MENSTRUATING ENDOMETRIUM

The main features may be summarized as follows. Endometrial transplants were observed in the eyes of six monkeys. Vasoconstriction began from six to twelve hours before the onset of menstruation and persisted throughout the first day. Menstruation began in the endometrium implanted in the eye, sometimes three hours before blood from the uterine hemorrhage entered the vagina. When several transplants were made into the same eye, the onset of menstruation was not simultaneous in all. Subepithelial hematomas formed and small papillae appeared on the epithelial surface. A papilla ruptured and hemorrhage continued for from twenty-five to seventy minutes. New ones formed and ruptured. Only a small part of a transplant bled at one time. (This explains the variability in different regions of the same endometrium recently stressed by Bartelmez.³) No desquamation of epithelium occurred during the first few hours and only small bits during the first day. There was much variation in the amount of tissue desquamated. Reepithelization occurred from outgrowths of free extremities of glands. This description further justifies the characterization of menstruation as a unique physiologic hemorrhage.

There are several operative procedures that will precipitate menstruation in normal adult primates: ovariectomy,⁴ damage to large follicles,⁴ excision of corpora lutea,⁵ and section of the nervous connections to the ovaries either peripherally⁶ or in the spinal cord.⁷ Section of the spinal cord precipitates menstruation but does not terminate the menstrual function, for regular cycles are resumed later.⁷ Since the menstrual hemorrhage is the most obvious feature, it has been greatly emphasized, and the whole cycle of endometrial changes has been dated from the onset of bleeding. Physiologically, however, menstruation is the last event, not the first in the menstrual cycle.⁸

From the Department of Anatomy Yale University School of Medicine. This paper logically follows a discussion of the Physiology of Endrogenic Principles earlier in this series.

MENSTRUATION INDUCED AFTER OVARECTOMY BY ESTROGENIC SUBSTANCE

The essential features of the endocrine mechanism controlling the menstrual cycle have been worked out experimentally,⁹ and the analogy to the estrous cycle of lower mammals has been clarified.¹⁰ Recently, Goodman and Wislocki^{10a} have added the spider monkey to the number of primates known to menstruate. They discovered by microscopic examination of material obtained from the vagina by the lavage method that a slight hemorrhage appears periodically which is seldom apparent externally. Although slight in amount, this hemorrhage may be an intermediate stage in the development of typical menstrual function. In women¹¹ and in monkeys,¹² after menstruation has disappeared following ovariectomy, it can again be induced experimentally by treatment with estrogenic substance. The important reaction here, as mentioned in the section of this series concerned with the estrous cycle of lower mammals,¹³ is stimulation by the injected hormone of a general growth reaction in the accessory genital organs: vagina, uterus, uterine tubes and mammary glands. Extremely rapid hyperplasia in the endometrium is indicated by the extraordinary number of mitotic figures. After this growth has been induced, either decrease in the dosage (Hisaw) or cessation of injections of the estrogenic substance is followed by menstrual hemorrhage.¹⁴ Even when this hormone therapy is continued at a uniform level by daily injections menstruation may appear.¹¹ Abnormal endometrial conditions have been produced by long continued injections.¹⁵ Many details as to optimum dosage, absorption of injected hormone and similar variables need further clarification. It is clear, however, that this hormone must act on the uterus before the onset of menstruation. The growth phase is therefore the first stage of the menstrual cycle, and menstruation the last stage.

CORPUS LUTEUM HORMONE NOT ESSENTIAL FOR MENSTRUAL HEMORRHAGE

That the ovarian follicular hormone is the necessary ovarian endocrine factor has been shown by the definitely established fact of menstruation without ovulation, and therefore without corpus luteum formation, as a frequent occurrence in normal monkeys,¹⁶ and as an occasional occurrence in women,⁸ and also by the

induction of menstruation in both monkeys and women by therapy with theelin alone.¹⁷ That the endocrine function of the corpus luteum is involved, when ovulation does occur, in either a supplementary or a regulatory capacity, is indicated by postponement of the experimental menstrual periods that should follow theelin therapy by superimposing progesterin (or theelin) treatment.¹⁸ Apparently the actual process of menstrual hemorrhage with or without a previous ovulation is fundamentally the same. The premenstrual or progestational transformation of the endometrium under the action of the corpus luteum hormone, though occurring normally in a fertile cycle, is not a necessary forerunner of the events leading to the actual hemorrhage.

VASCULAR AND GROWTH EFFECTS

As described in the section on estrogenic principles, vasodilatation of the vessels of the rabbit's endometrium has been included as one of the principal reactions following injections of theelin.¹⁰ Therefore, operative procedures that interfere with secretion of the estrogenic factor in the normal animal, or cessation of theelin treatment or decreased dosage of either theelin or progesterin during replacement therapy in ovariectomized animals, might well explain the vasoconstriction observed immediately preceding onset of the flow.

It should be further stressed, however, that after destruction of the outer layers of the endometrium, new growth of vessels is required to sustain the rapid repair and growth of the endometrium for the next cycle. The growth of these new capillaries and the changes in the arterioles, with distribution of longitudinal muscles in their walls as in erectile tissue, has been stressed in relation to the control of menstrual hemorrhage.² This further emphasizes the importance of the preliminary growth phase, which precedes menstruation.

THERAPY WITH ESTROGENIC SUBSTANCE IN WOMEN

Probably the most successful therapy in women with theelin alone aimed at alleviation of operative menopause symptoms following complete ovariectomy is that reported by Werner and Collier.¹¹ They demonstrated considerable growth in the genital organs of ovariectomized women induced by daily injections of a crystalline preparation of theelin. Menstruation appeared both during the course of injections and after the cessation of treatment. For controls in Werner and Collier's experiments, biopsy specimens were taken before injections were begun, which showed the atrophic endometrium of the typical castrate. Other biopsies taken periodically during the course of injections showed marked hyperplasia. The degree of development induced in the endometrium was equivalent to that of the normal intermenstrual stage—there was no progestational transformation. There was a definite increase in vascularity and size of the cervix and a noticeable growth of the mammary glands. The experimental menstrual hemorrhage was qualitatively indistinguishable from the menstrual discharge of normal women. There was a distinct alleviation of the usual subjective menopause symptoms. In some instances there was a decided increase in libido.

19 Markee J. E. Rhythmic Vascular Uterine Changes Am. J. Physiol. 100:52 (March) 1932

In later experiments, Werner and Collier²⁰ reduced the dosage somewhat but still obtained results that confirmed the conclusions of their first report. They suggest about 2,800 rat units of theelin as the minimum clinical dosage over an interval of from two to four weeks.

Among the many other reports of clinical trials of estrogenic preparations, the recent paper by Papanicolaou is of interest. Although the wave of growth in the vaginal epithelium is not so clear-cut in primates as in rodents, careful examination shows a cyclic fluctuation in both growth and desquamation (Corner,¹⁸ Allen,⁴ Hartman,^{20b} Papanicolaou²¹). By this method of examination, effects of injected estrogenic preparations may be followed in clinical tests.

Another extremely good indicator of follicular hormone concentration in experiments with monkeys is the reddening and swelling of the "sexual skin." In the normal animal these phenomena are more intense during the intermenstruum.²² As the time for menstruation approaches, the color becomes paler and swelling decreases.⁴ The reddening and swelling can be induced after ovariectomy by injections of estrogenic substance.⁴

In my opinion the experiments of Werner and Collier are of great significance because they extend a demonstration of the essential mechanism of menstruation to women. However, since absence of menstruation is compatible with good health, there seems little reason for attempting to reestablish menstruation as a routine therapeutic procedure after complete ovariectomy. The treatment at best can only be temporary, and the value (other than psychologic) of experimental menstrual periods in such patients is still problematic. It is good, however, to know that it can be done.

SYNERGISTIC ACTION OF FOLLICULAR AND CORPUS LUTEUM HORMONES

Work on purification and standardization of corpus luteum hormones has advanced rapidly.²³ Typical progestational endometrium has been produced in ovariectomized monkeys by successive theelin and progesterin injections,²⁴ and similar well controlled experiments have been reported in ovariectomized women.²⁵ If progesterin is to be used therapeutically, it is obvious from the experiments in monkeys and rabbits that it should be preceded by treatment with estrogenic substance unless there are indications that ovaries in situ are providing this necessary preliminary growth stimulus. Furthermore, a proper balance between these hormones is essential, for estrogenic substance has been demonstrated in the human corpus luteum during the

premenstrual stage of the menstrual cycle.²⁶ Much work will be required to determine the optimum clinical dosage. These two hormones are closely related in chemical structure. That they are secreted by the same cells in different phases of life (follicular and luteal) suggests the possibility that progesterin may be formed by a change in the molecule of the estrogenic hormone.

DEPENDENCE OF OVARIAN ENDOCRINE FUNCTION ON ANTERIOR PITUITARY

It seems to be well established now that secretion of the ovarian hormones from both follicles and corpora lutea is dependent on the normal function of the anterior pituitary.²⁷ Treatment with estrogenic substance has not been effective in producing experimental menstrual periods in ovariectomized monkeys if they have also been hypophysectomized.²⁸ Furthermore, injections of estrogenic substance do not increase function of the ovary itself.²⁹ If ovarian therapy succeeds in establishing growth of genital tissues followed by menstruation, only a temporary effect is to be expected.

Smith and Engle followed their demonstration of the anterior pituitary effects on the ovaries of the rat by convincing experiments in monkeys.²⁹ They induced intense follicular hormone reactions by anterior pituitary stimulation of the ovaries, then terminated the follicular phase by ovariectomy, and menstruation followed. Injections of theelin, however, following ovariectomy delayed the onset of the experimental menses. Engle³⁰ reported the interesting experiment of injecting anterior pituitary-like gonadotropic substance from pregnancy urine. He was able to induce experimental menstruation without changing the secondary sex characteristics of the "sexual skin." Hisaw,³¹ with the use of pyridine extracts of anterior pituitary, stimulated follicular growth which resulted in reddening and swelling of the "sexual skin" followed by menstruation.

EXPERIMENTAL OVULATION OF MORE THAN THE USUAL NUMBER OF EGGS

Following the demonstration of the striking effect of the anterior pituitary upon the ovaries, especially Engle's production of superovulation in the mouse,³² attempts were made to induce the monkey to ovulate more than one or two eggs at a time.³³ The earlier attempts resulted in cystic follicles without ovulation. Hisaw, Greep and Fevold finally succeeded in inducing a monkey to ovulate a "litter" of eight eggs by the proper balance of follicle-stimulating and luteinizing fractions of anterior pituitary extracts.³⁴ This work of

Smith and Engle and of Hisaw in producing ovulation of more than the usual number of eggs has far reaching implications for the problem of sterility. Insufficiency of the anterior pituitary gonad-stimulating hormone may explain the frequent anovulatory menstrual cycles of monkeys.

TIME OF OVULATION IN THE MENSTRUAL CYCLE

Evidence placing the time of ovulation in the menstrual cycle has been accumulated for the monkey (Corrigan,³⁵ Allen,⁴ and Hartman^{16b}). Hartman's method of rectal palpation in the monkey has determined ovulation time without laparotomy in successive cycles in the same animals. For woman, in addition to data as to age of corpora lutea, definite evidence in the form of recovery of eggs from the uterine tubes has been presented by Allen, Pratt Newell and Bland³³ and by Warren Lewis.³⁶ Ovulation occurs most frequently at the approximate midpoint between onset of two successive menses.

ENDOCRINE INFLUENCE ON SEX URGE

Although the statement is usually made that there is no period of estrus, a restricted period of increase in mating instincts, during the menstrual cycle, Ball and Hartman³⁷ have recently shown that just before ovulation in the monkey there is a definite rise in sex desire. Most primates, however, will allow copulation at any time in the menstrual cycle. Mating instincts are easily induced in ovariectomized rats and mice by injections of large amounts of estrogenic material.³⁸ Other reports have confirmed and extended these observations. The reader is referred to a recent review by Seward.³⁹

SUBJECTIVE SYMPTOMS

As to the subjective symptoms that accompany menstruation and its cessation after the menopause, considerable caution must still be used. Analyses of blood and urine show a diminution of secretion of estrogenic substance after the menopause.⁴⁰ Beneficial results have been reported from theelin therapy.⁴¹ An extensive clinical trial of theelin has been made recently by Severinghaus.⁴² He recommends therapy with estrogenic substance for the alleviation of severe menopause symptoms. He finds that small doses which are insufficient to produce menstruation or to increase libido may be effective for relief of vasomotor and mental symptoms. This phase of the problem is an extremely difficult matter to evaluate, but it cannot be dismissed lightly. The psychologic side of the menopause with the depressions accompanying involutional bodily conditions are recognized as serious factors by both gynecologists and psychiatrists. Hormone therapy may be

useful for a transitional period until a compensatory endocrine balance is reached or a more gradual psychotherapy can be undertaken.

OPTIMUM DOSAGE AND EXCRETION OF ESTROGENIC SUBSTANCE

So far, attempts to reduce excessive uterine hemorrhage in woman with theelin therapy have not proved very effective. That some types may be due partly to abnormal endocrine function involving secretion of estrogenic hormone is indicated by increased excretion of hormone in some of these cases.

The optimum dosage of estrogenic substances must be given further experimental test. Analyses of hormone content of the blood and of urine indicate that there may be cyclic fluctuation in the estrogenic hormone secreted in the normal female.⁴³ Should the clinical dosage be designed to simulate this periodic increase or should the dosage be continued at uniform levels? Until more is known about the absorption of injected extract from subcutaneous or intramuscular sites, the rapid disappearance of injected hormone from the circulation and the control of excretion of the hormone, the matter of dosage must still continue on an empirical basis. Now that quantitative analyses of extremely small amounts of estrogenic substances are possible in twenty-four hour samples of urine,⁴⁴ it will be possible to check the matter of possible overdosage from injections of large amounts of theelin in water soluble preparations. One thing that has definitely been decided is that such huge doses of theelin as computed for women on the basis of ratios of body weight to that of small laboratory animals are not required. From 50 to 400 rat units of hormone daily seems to be adequate in most cases for the reestablishment of menstruation and relief of subjective symptoms, especially if atrophy following ovariectomy or the menopause is not too far advanced. Even smaller doses may be effective for other theelin effects than the reestablishment of menstruation, for there undoubtedly exists a difference in threshold level for various reactions to this hormone.

VARIATIONS IN REACTIVITY

Variations in the reactivity of certain organs to hormones during long periods of treatment require further extensive consideration. Also the possibility of the development of some sort of immunity in long continued hormone treatment must be tested further.⁴⁵ Since theelin is a crystalline preparation free from proteins, this whole matter must be carefully investigated before generalizations are possible. A recent report indicates that injections of estrogenic substance do not result in the formation of antihormones.⁴⁶

CONCERNING THE PRIMARY CAUSE OF SEXUAL RHYTHMICITY

In looking for the primary cause of the rhythmic nature of menstrual processes, attention has been focused on the anterior-pituitary gonad-stimulating function. A variation in the amount of gonad-stimulating substance in the pituitary at different times in the

estrous cycle has been demonstrated⁴⁷ When no obvious reason for this change could be found inherent in the pituitary itself, the theory of mutual reaction between anterior pituitary and gonads was introduced to explain female sexual rhythmicity Then it was demonstrated that removal of the ovaries increases the power of the anterior pituitary to stimulate the ovaries,⁴⁸ and that injections of estrogenic hormone would decrease this gonadotropic function⁴⁹ This resulted in the theory that the anterior pituitary stimulates the gonads to secrete a specific hormone, which in turn depresses the gonad-stimulating secretion of the pituitary⁴⁹ With the demonstration, especially by Hisaw and his collaborators, of the two pituitary factors influencing the ovaries, the follicle-stimulating and the luteinizing factors, this theory of interaction must be expanded further The demonstration of the balance of these purified extracts necessary to induce ovulation in the monkey⁵⁴ and cat⁵⁵ seems conclusive It would seem that the follicle-stimulating hormone of the anterior pituitary induces growth of follicles and secretion of follicular hormone, which in turn reacts on the pituitary to induce secretion of the luteinizing factor This aids development of the corpora lutea, which produce progesterin The follicular hormone (and possibly progesterin also) may act on the pituitary temporarily, depressing its secretion of follicle-stimulating hormone until released from the influence of gonad hormones Although the interaction of pituitary and gonads seems complex at present, extremely rapid recent progress encourages the belief that continued accumulation of experimental evidence will clarify our understanding of this mechanism The time required for growth of both follicles and genital organs must be considered in any working theory In my opinion, the decrease in the level of follicular hormone, after a certain amount of growth has been induced in the endometrium, seems well established as the ovarian cause of menstruation

CONCLUSION

To date the greatest practical value of replacement of ovarian function with hormones has come from providing a foundation of experimental evidence for understanding the basic endocrine mechanism of the menstrual cycle The "interval" stage of the old classification based on morphologic study of the endometrium may well be omitted

The menstrual cycle in the endometrium, when considered from the point of view of the ovarian endocrine mechanism responsible, should be characterized as follows

Stage 1 A period of postmenstrual growth and serous secretion of the glands is the preparatory event This is the follicular phase under the stimulus of the estrogenic factor

Stage 2 (a) If ovulation occurs a gradual transition leads to a period of transformation of glands, with change in the nature of their secretion This is the luteal stage, under the supplementary stimulus of progesterin (with some estrogenic substance still present in woman) It should be recognized that this second stage is not necessary for menstruation

(b) If ovulation fails to occur, there follows a phase characterized by sustained but waning hyperplastic endometrium under the influence of diminishing concentration of estrogenic hormone from follicles in regression This type of cycle is normal in monkeys out of breeding season and is an occasional occurrence in adult women and may be a frequent occurrence near the times of puberty and the menopause

Stage 3 The menstrual hemorrhage is physiologically the terminal event of the cycle

Although histories of menstrual cycles will probably continue to be counted from the onset of hemorrhage, the place of menstruation as the last phase of the cycle, possible only after endometrial growth under the action of the estrogenic hormone, seems clearly established

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
HOWARD A. CARTER Secretary

BURDICK THERAPEUTIC BAKER ACCEPTABLE

Manufacturer The Burdick Corporation, Milton, Wis

This device is a very practical variety of therapeutic baker It is approximately 24 inches high, 18 inches wide and 30 inches long It may be extended $4\frac{1}{4}$ inches higher The reflector is nickel plated inside, and there is an air space between the reflector and the outside hood It is equipped with eight carbon filament lamps of 60 watts capacity The entire baker is rated at 660 watts, 110 volts There is a dual switch, which enables the operator to switch on four or eight lamps at a time

The unit has been tested for its electrical consumption It was found that with all lamps burning on a 110 volt line the current reading was 38 amperes, or approximately 420 watts The unit is finished in white enamel and is of rugged construction Its weight is about 25 pounds In view of the usefulness of the unit, the Council voted to include the Burdick Therapeutic Baker in its list of accepted devices

AURATONE NOT ACCEPTABLE

Manufacturer The Auratone, Inc., Grand Rapids, Mich

Claims are made for the Auratone that it will determine relative hearing ability of individuals afflicted with deafness and that it will correct defects in hearing by administering controlled vibrational exercises

The unit was investigated in a physical laboratory acceptable to the Council The report stated that the Auratone appeared to give consistent results, as far as frequency and volume were concerned The same frequency and the same volume within reasonable limits of observation, were observed with dials set at the same position from day to day These results were checked by means of an oscilloscope and an oscillator

The device was placed in a clinic acceptable to the Council to determine the value or possible harmful effects of the Auratone as a method of treating deafness Treatment by this instrument consists in running an ascending and a descending scale of musical tones determined by the limits of the machine, that is from a low frequency of about 124 to a high frequency of slightly over 2,000

This investigation covering a period of about ten months, consisted in giving a total of 777 treatments to both ears¹ of twenty-five partially deaf people An average of thirty-one treatments was given the patients The types of deafness were not selected but were taken as the individual applied to the clinic A clinical diagnosis of nerve type deafness was made in fourteen of the patients, three had a diagnosis of otosclerosis one patient seemed to have a combined otosclerosis

¹ In two instances only the right ears were treated

⁴⁷ Smith P. E. Evidence of a Correlation Between the Amount of Gonad Stimulating Hormone Present in the Pituitary of the Guinea Pig and the Stage of the Reproductive Cycle *Anat Rec* 42: 38 1929

⁵⁰ Foster M. A. and Hisaw F. L. Experimental Ovulation and the Resulting Pseudo-Pregnancy in Anestrous Cats *Anat Rec* 62: 75 (April) 1935

and chronic middle ear deafness, three had what seemed to be a mixed type of deafness, that is, a partial nerve deafness and a partial chronic adhesive otitis media. Two patients were diagnosed as having chronic middle ear deafness. One patient had had a sudden attack of deafness, tinnitus and vertigo resembling Ménière's syndrome. One other patient had a nerve type deafness of twenty-five years' standing but with a sudden onset with symptoms of Meniere's syndrome. All the patients were adults, their ages ranging from 25 years to 76 years, with an average age of about 49 years.

An effort was made to give the treatments or "exercises" three times a week. Some of the patients came two times a

Chart 1—Average of twenty five patients before treatments with Auratone

week and some were intermittent in their attendance, with occasional lapses.

Graphs of hearing in each ear as determined by the 2-A Audiometer were taken of each patient before treatment was begun. Additional graphs have been taken about every ten treatments. Special effort was made to exercise the areas of more marked deafness. Care was taken to give only sufficient volume to be comfortable to the patient, as it was felt from former experiences that a detrimental result might follow with excessive amplitudes.

Chart 1 is an average of twenty-five patients taken before treatments were begun. Chart 2 is an average of these twenty-

Chart 2—Average of twenty five patients after treatments with Auratone

five patients after they had had from ten to seventy-seven treatments each.

An average of the various frequencies in both ears before treatment compared with an average of the frequencies in both ears at the end of the treatment period gives an average loss of 3 3/4 sensation units for each frequency of 64 to 8,192 inclusive. However, five patients who had had from twenty-six to forty-one exercises showed an average improvement of 3 sensation units in the voice range of frequencies.

Many of the patients seemed to think they could hear better after the treatments. However, this does not seem to be borne out by the Audiometer.

In view of the foregoing, the Council voted not to include the Auratone in its list of accepted devices for physical therapy, because, as a method of treating deafness it has not proved of value in the cases treated.

Council on Pharmacy and Chemistry

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS

PAUL NICHOLAS LEECH Secretary

HEXYLRESORCINOL SOLUTION S T 37 OMITTED FROM N N R.

Hexylresorcinol Solution S T 37 was accepted by the Council in 1928 as a dosage form of Caprokol (Sharp & Dohme). The product is a solution of Caprokol (Hexylresorcinol S & D) 1 part in a liquid composed of glycerin 30 per cent and water 70 per cent, 1,000 parts. The expression "S T 37" was at that time accepted as an abbreviation for the surface tension of the solution, which is 37 dynes. It was stipulated that the use of the term "S T 37" was not to be preempted, and that the product should not be referred to as "S T 37" but as "Hexylresorcinol Solution S T 37".

The acceptance of Hexylresorcinol Solution S T 37 expired with the close of 1931. Since that time the product has been retained in N N R by sufferance, pending settlement of the various objections and new considerations raised by the firm in regard to the conditions on which the Council voted to reaccept it. The status has therefore been that of a nonreaccepted product.

After much discussion and correspondence, Sharp & Dohme definitely refused to comply with an essential condition on which the Council was forced to base the reacceptance of Hexylresorcinol Solution S T 37, namely, discontinuance of the expression "S T 37" in connection with the name of the product. This will be discussed later. Other matters questioned in the Council's reconsideration of Hexylresorcinol Solution S T 37 were:

- The claims of efficacy permissible for the product.
- The use by the firm of advertisements featuring the use of the product in great hospitals.

CLAIMS OF ANTISEPTIC AND GERMICIDAL EFFICACY

No claim for Hexylresorcinol Solution S T 37 as such was given in the New and Nonofficial Remedies description of the product Caprokol (Hexylresorcinol-Sharp & Dohme), its chief constituent, is stated to possess marked germicidal properties, but equal efficacy could not, of course, be ascribed to a one-tenth per cent solution (1 part of Hexylresorcinol [Caprokol] in 1,000 parts of a solution containing 30 per cent glycerin). The Council recognized the claim of Sharp & Dohme that the reduction of surface tension in the glycerin solution increased the germicidal power. In reviewing the advertising of the firm at the time of reconsideration, the Council found that certain limitations were needed. The Council adopted the following statement of limitations, which was transmitted to Sharp & Dohme:

- that the surface tension reducing properties of Hexylresorcinol (Caprokol) are advantageous in aiding this germicide to come into contact with bacteria
- that solutions of this substance (including the 1:1,000 solution in 30 per cent of glycerin) are aided by the surface tension reducing properties to penetrate small cracks and crevices
- that within the resorcinol series of compounds up to the heptyl derivative, there is a parallelism between surface tension reducing properties and germicidal action
- that claims may not be based on the comparison of disinfectants solely in terms of their ability to reduce surface tension, or based specifically on the particular surface tension value of the Sharp & Dohme 1:1,000 solution of Hexylresorcinol in 30 per cent glycerin
- that Caprokol (or Hexylresorcinol Solution) has not been shown on internal administration to produce analgesic action on the genito-urinary tract
- that claims for analgesic action of the solution applied for short periods in gargles or in other ways to mucous membranes are not acceptable unless there is direct convincing evidence that analgesia is produced by the particular method of application
- that the claim for a moderate (limited) but distinct analgesic action for this solution when applied continuously as a moist dressing to burns, scalds and inflamed surfaces is acceptable, and
- that recommendations for application of Hexylresorcinol Solution to the conjunctiva should be accompanied by reference to the considerable though brief irritation caused by such application

The firm has repeatedly signified its intention of meeting these limitations in advertising of the product but has not done so, and at the time of the omission of Hexylresorcinol Solution S T 37 from N N R nearly two years later it still had not put into effect many of the limitations set forth

ADVERTISEMENTS FEATURING "GREAT HOSPITALS"

For some time the Council's office has been receiving letters from physicians objecting to advertisements of Hexylresorcinol Solution S T 37 in lay publications featuring the use of the product in certain hospitals in such a way as to make this use an endorsement to influence lay persons to use the product. The Council's referee reported the matter to the Council as follows

In order to show the basis for the objections which have been made to the Council the text of the advertisement from the September 1933 issue of *Hygeia* is herewith reproduced

Used Daily by leading Specialists at the Grace Hospital New Haven
Use it in your own home

Hexylresorcinol Solution S T 37 is used regularly for its great germ-destroying power combined with safety
Grace Hospital New Haven Conn

The Grace Hospital in New Haven Conn., justly priding itself on its splendid modern equipment and unrivaled medical care is still another of the great hospitals regularly using Hexylresorcinol Solution S T 37 (1 1000)

This hospital says So powerful is this antiseptic that it is used here daily for the cleansing of wounds and in operations. This efficient antiseptic spreads more rapidly and more deeply than many other antiseptics into the crevices of wound tissue

Hexylresorcinol Solution S T 37 is stronger than carbolic acid in any usable solution—yet so safe, you can use it freely in your own home.

Pour it at once into scratches cuts open wounds In case of serious injury consult your physician Hexylresorcinol Solution S T 37 does not sting or burn Teach your children to use it freely The seal of the Council on Pharmacy and Chemistry of the American Medical Association should serve as an indication of its trustworthiness

Hexylresorcinol Solution S T 37 is economical The 50c bottle is now a whole 25 bigger than before And you get the large size for only \$1.00 instead of \$1.25 Prices are now the same in both the United States and Canada Buy a bottle today!

Hexylresorcinol Solution S T 37 [Picture of bottle.]

Made by Sharp and Dohme [The seal of the Council]

The salient features of this text are

1 An advertisement of the Grace Hospital of New Haven as another of the great hospitals' having splendid modern equipment and unrivaled medical care.

2 A statement that Hexylresorcinol Solution S T 37 is used daily in this hospital by leading specialists

3 Several statements of claims for Hexylresorcinol Solution S T 37 as a powerful antiseptic, as a substance which spreads rapidly and deeply into the crevices of wound tissue as a preparation combining great germ-destroying power with safety These claims although expressed in the stock phrases of the manufacturer are published as quotations from the Grace Hospital

4 Claims for the product made by the manufacturer

5 Directions for use of the solution by laymen

6 Imperative recommendations for the layman to use it in his home and to teach his children to use it freely

7 A statement that the Council's seal should serve as an indication of the trustworthiness of the solution

The firm received permission to use the name of the hospital photographs taken in the hospital and to quote the hospital An affidavit in this effect including the quoted statements was given by Mr H V Whipple who was superintendent of the Grace Hospital on June 28, 1933 the date of the signing of the affidavit It will be shown that this affidavit cannot cover all the statements in this advertisement.

The referee has the following objections to the advertisement

1 Without prejudice to the Grace Hospital, it seems to the referee inappropriate for one of the American Medical Association publications to advertise this hospital as one of the great hospitals with unrivaled medical care unless the hospital has been examined to determine the truth of the claim. The referee understands that this was not done in this case. Furthermore it seems to the referee not in good form to advertise a hospital in this manner

2. The advertisement is the publication of a sort of double testimonial a testimonial from a personified hospital and a testimonial from unnamed specialists Sharp & Dohme has in the past used testimonials abundantly The Council has never approved of them and has specifically required the firm to abandon their use in advertisements The firm has discontinued numerous testimonial pamphlets in conformance with the Council's requirements but continues to use this type of testimonial

The use of hospital endorsements of Hexylresorcinol Solution was a subject of special investigation by the Council in 1932 Answers to a questionnaire disproved most of the firm's statements that great hospitals were using the preparation It appeared to be especially objectionable for the firm to quote or so to arrange phrases as to give the laymen the impression that since the solution was used in some great hospital it should be used freely at home by laymen.

3 The statements quoted as coming from the Grace Hospital setting forth the antiseptic, germicidal spreading and penetrating powers and safety of the preparation are expressed in well known words of the firm's advertising copy writer The point here is Does the hospital know from the results of its own tests that these statements are true? A hospital should state only the results of its own experience an advertisement containing the endorsement by a hospital may be acceptable only to the extent to which it gives expression of the hospital's actual knowledge It seems obvious from the text of this advertisement that the hospital is using phrases furnished by the manufacturer The affidavit does not include any affirmation that these properties of the solution were determined by experiment in the hospital Whether the hospital has made necessary tests could be determined by inquiry Sharp & Dohme should be informed that the Council considers it misleading for a firm to credit to second parties statements that are lifted from the claims of the firm itself

4 The statement of the significance of the Council's seal in this advertisement appears to the referee to be objectionable both on account of the context of the paragraph in which the statement occurs and because of the phraseology The sentence is cleverly written in the conditional mode. Nevertheless the reference to trustworthiness seems to go beyond the statement as to the significance of the seal regarded as permissible according to New and Nonofficial Remedies 1933 page 12 It is stated there that a firm may refer to the significance of the seal as follows "The accepted seal denotes that (name of article) has been accepted for New and Nonofficial Remedies by the Council on Pharmacy and Chemistry of the American Medical Association and that 'further statements in regard to the seal must be submitted to the Council and found acceptable before they may be used' The Council has taken no action justifying the firm's advertisement to the lay the implication that the Council vouches for the 'trustworthiness' of the preparation in all sorts of scratches cuts and open wounds and in the miscellaneous free use of the solution by children

No objection can be raised to the parts of the advertisement which give direct statements on the use of the solution in the Grace Hospital and the firm's claims for the preparation which are permissible under the description in New and Nonofficial Remedies

The Council voted 1 That the advertising department of the American Medical Association be informed that the Council does not approve of certain features of the Grace Hospital Hexylresorcinol Solution S T 37 advertisement published in *Hygeia* September, 1933, for the reasons set forth in this report 2 That Sharp & Dohme and any other firms submitting advertisements containing hospital endorsements be informed that the Council regards such advertisements as unacceptable testimonials unless the statement of the endorsement is limited to the name and place of the hospital a simple statement of the use of the preparation in the hospital and statements of properties and results supported by reports of actual tests made in the hospital Advertisements mentioning a hospital must also conform to the type deemed permissible under the Principles of Medical Ethics issued by the American Medical Association 3 That the Council regard as unacceptable the use of a hospital's endorsement of a preparation as a general recommendation for free application of the preparation in the layman's home. 4 That as a general rule the Council will not deem acceptable advertisements from manufacturing firms containing statements extolling the equipment medical service or other conditions of a hospital and the Council further voted that the Council may approve of an advertisement containing a hospital endorsement of a preparation provided the advertisement is limited to a direct statement based on the hospital's use of the preparation and tests of its properties and does not conflict with any of the general rules and special requirements of the Council

A member of the Council in discussing the report, commented that such a statement should be signed by the individuals who did the work

THE OBJECTIONS TO S T 31

During 1931 the dangerous and confusing multiplication of number and letter abbreviations had prompted the Council so to extend its enforcement of its rule 8 as to provide against the use of letters and numerals in the names of products The Council had always held this objectionable because of the tendency to substitute them for the actual name which in the case of Council accepted products is required to be informative The following proposed revision of the rules was adopted

Since the use of numeral or alphabetical designations in connection with drug names tends to take the emphasis away from the name and to displace the name thus leading to confusion the Council will not recognize the name of a drug in which the numeral or letter is an integral part of the name except in special cases in which the use of a numeral or letter seems desirable because further improvement of the product is anticipated in which case the Council may grant a special exemption from the rule. Under this rule the use of numerals or letters in connection with the name of a product will not be permitted on labels or in advertising unless the numeral or letter is clearly separated from and subordinated to the name by type, and if feasible by position

Since the reacceptance of Hexylresorcinol Solution S T 37 was being considered, the Council voted that the manufacturer be required to meet the following conditions with regard to the name before the product could be reaccepted

- to adopt the simple name Hexylresorcinol Solution
- to agree to discontinue the use of the abbreviation S T 37 in the name on the label and in all advertisements circulars and pamphlets relating to this preparation

- (c) to print the statement "surface tension 37 dynes in type smaller than the name and separated from the name on labels, circulars, pamphlets and advertisements, and
- (d) to complete these changes before a specified date

When the firm was informed of these conditions, it raised the objection that the Council had previously recognized the use of the expression "S T 37" and in consequence that permission to use it should not be revoked.

The Council took cognizance of the firm's contention that it had accepted the name Hexylresorcinol Solution S T 37. In counterargument it was pointed out that the Council's agreements are limited to three years, with a reservation that this term may be shortened if new facts come to light. The rules state expressly that the Council will enforce any new rules when the three year period has expired. The clause referred to reads:

Any amendments to the rules by specific requirements or by interpretation which may be made after the acceptance of an article, shall not apply to such article until the period of acceptance has elapsed. At the end of this period the article if it is not eligible under the amended rules will be omitted.

This leaves no doubt as to the right of the Council to enforce new rules.

It is true that special leniency has been extended to proprietary names that were established before the rules were promulgated, this leniency being justified by the vested interest in such names and the losses which changes would entail. However, when the Council adopted the ruling to exclude numbers and letters from names, it did not exempt established preparations, and properly so, because it had never accepted the use of such devices as an integral part of a proprietary name. It was merely clarifying a situation which had undesirable implications. Manufacturers in general seem to have accepted this as a just ruling, especially as the Council has been liberal in giving time to effect the change without unnecessary hardship—and the Council indicated its intention of doing so in the case of Hexylresorcinol Solution S T 37. It became clear that the difficulty in the Council's reconsideration of Hexylresorcinol Solution S T 37 has arisen because the firm had broken a rule of the Council, which was in force when "S T 37" was first accepted, and against which the manufacturer had been specifically warned, but which it violated without notice to the Council. In brief, the firm had been warned that "S T 37" could not be accepted as a proprietary (i. e., protected or monopolistic) name because the rules prohibit the use of two proprietary names for a given substance. The Council had accepted the use of the letters as part of a descriptive non-proprietary name because the firm has already preempted its proprietary name "Caprokol Solution" for an oily solution and because it seemed fair that attention should be called to the special property represented by the abbreviation. Notwithstanding these warnings, it appears that the firm copyrighted the expression "S T 37" (without the knowledge of the Council—in fact the Council was not informed of this step until it came to light in the present controversy) and thus made it a proprietary name instead of a description of a property and applied it to articles, such as a tooth paste, which could not have the surface tension quality for the description of which the abbreviation had been accepted. The legality of trademarking a descriptive name is itself doubtful, but there seems no doubt that the firm permitted the Council to believe that it was using a nonproprietary name when, in fact, it had converted this in a proprietary name. Had the firm abided by the rules—which, it is believed, were fully understood on its part—no difficulty would have arisen for there would now be no special interest in retaining the letters "S T 37," which any one could use. Since the physical property to which the firm intended to call attention has ceased to be a novelty, the only interest which the firm has in retaining these letters is the interest which it secured by the apparently secret violation of the Council's rules.

The foregoing reasons for the Council's decision were communicated to Sharp & Dohme and were the subject of correspondence between the Council and the firm. In the end, the firm informed the Council that it could not agree to discontinue the use of the objectionable expression "S T 37" in the name of the product. In the public interest, the Council was therefore compelled to omit from New and Nonofficial Remedies the product which had been accepted as "Hexylresorcinol Solution S T 37."

SUBSEQUENT CONSIDERATION

When a report of the foregoing decision of the Council was sent to Sharp & Dohme, the firm replied that it desired to publish an advertisement in *THE JOURNAL* and in all publications of the American Medical Association. The Council felt, and the Trustees of the Association concurred, that as this advertisement obscured and thereby misrepresented the essential point at issue, it should not be accepted as an advertisement, but that its wording might be appended to this report, so that those who have read the foregoing article may also have before them the point of view of the manufacturers. This wording is as follows:

"A STATEMENT FROM SHARP & DOHME TO THE MEDICAL PROFESSION

The Council on Pharmacy of the American Medical Association has recently revised Rule 8 to prohibit the use of letters and numerals as an integral part of a product name.

Since the Council has stated that it cannot make permanent exceptions to any of its rules, this revision of Rule 8 operates retroactively and therefore renders the established name HEXYLRESORCINOL SOLUTION S T 37 and the product so named, ineligible for further inclusion in New and Nonofficial Remedies.

Sharp & Dohme has been forced therefore to regret fully submit to the omission of Hexylresorcinol and its previously accepted dosage forms from N. N. R. and so notified the Council on January 12, 1934.

We wish to emphasize the fact that the product and the claims made for it during six years of Council acceptance remain unchanged, the sole reason for this action on our part being the conflict between an established name and a new Council rule as to nomenclature.

SHARP & DOHME
Philadelphia
Baltimore

[END OF PROPOSED ADVERTISEMENT]

All the points raised by the firm had been already answered in the Council's report, but it seems advisable to recapitulate them:

(1) The advertisement gives the impression that Rule 8 has been recently revised. The correct statement would be that Rule 8 was revised in January 1932.

(2) The advertisement gives the impression that revision of the Rule operates retroactively. In the opinion of the Council this is not an accurate statement since the Rule has been applied at all acceptance dates. The statement is particularly untrue with reference to Hexylresorcinol Solution S T 37. Hexylresorcinol Solution S T 37 was accepted for only three years. By sufferance it was kept in New and Nonofficial Remedies two years after the expiration of the last period of acceptance. At the time it was accepted it was stated clearly that the use of the abbreviated expression "S T 37" could not be preempted. Years later the Council was amazed to find that the firm had trademarked S T 37. When products are accepted for only three years there is no claim of retroactivity because the Council's rules specifically provide:

Unless otherwise determined at the time of acceptance Articles admitted to New and Nonofficial Remedies will be retained for a period of three years provided that during that period they comply with the rules and regulations which were in force at the time of their acceptance. At the end of this period, all articles will be carefully re-examined for compliance with existing rules. Any amendments to the rules by specific requirements or by interpretation which may be made after the acceptance of an article shall not apply to such article until the period of acceptance has elapsed. At the end of this period the article if it is not eligible under the amended rules will be omitted. (See N. N. R., 1934, pp. 13-14.)

Insofar as all measures which correct past undesirable practices are retroactive then the action of the Council could be considered retroactive but only in this restricted sense. The firm placed itself in the wrong by arrogating to itself, without notice to the Council, a proprietorship in the descriptive abbreviation "S T 37." The Council had not intended or conceded that the firm should have a proprietary right to this abbreviation of the name, and in fact repeatedly warned against the firm's taking this action. The chief deprivation as indicated by the foregoing advertisement concerning the Council's action,

is to take away from the firm something that had never existed so far as the Council is concerned. Indeed, had the Council known that the firm had secured a copyright on this abbreviation, even though this new number rule had not been passed, the name would have been subject to rejection. Furthermore, no other firm has refused to comply with the rule that numbers cannot be used for, or as part of, a name.

(3) The last paragraph of the advertisement is essentially true for the six years during which the product was accepted. But it fails to state that the claims remained practically the same although the Council repeatedly stipulated that some of them should be changed. Many forms of advertising were in fact discarded by the firm. Other claims to be questioned were not further considered because of the argument on the name.

A further report of the Council's proceedings in reference to Hexylresorcinol Solution S T 37 was conveyed to the firm of March 30, 1935. The firm replied (April 8).

We have nothing further to add except to reiterate that we have always been ready and willing to comply with every suggestion of the Council regarding our printed matter and promotional efforts relative to Hexylresorcinol Solution S T 37, with the exception of the change in the title of our established name for this product."

In the opinion of the Council the reply of the firm is only a reiteration of the argument which has been covered by the statements embodied in the preceding report. The Council reaffirmed its previous decision and authorized publication of the original report with the foregoing statement of subsequent consideration.

CAPROKOL OMITTED FROM N N R.

Caprokol (Hexylresorcinol-S & D) was accepted for inclusion in New and Nonofficial Remedies in 1924. The following dosage forms were accepted by the Council:

Capsules Caprokol (Hexylresorcinol-S & D) 0.15 Gm
Caprokol (Hexylresorcinol-S & D) 2½ per cent Solution in Olive Oil

Hexylresorcinol Solution S T 37

When the customary three year period of acceptance expired in 1931, the Council voted to reaccept Caprokol provided the manufacturers agreed to make a drastic revision in their advertising propaganda and to submit convincing evidence of the therapeutic value of the drug in all the numerous conditions in the treatment of which its use was recommended. Later, substantiation of the claims that the substance has analgesic action and has special germicidal properties due to its ability to lower surface tension were added to the requirements of the Council for the reacceptance of Caprokol. In the course of the next two years the firm omitted a number of the most objectionable circulars and submitted evidence on the question of the analgesic action. During this time, however, the firm did not submit any new evidence on the therapeutic value of the preparation in the treatment of genito-urinary infections and numerous other conditions in which its use was recommended as a beneficial germicidal agent.

In the discussion of claims made on the basis of the surface tension of both Caprokol and of the dosage form, Hexylresorcinol Solution S T 37, the question of nomenclature arose leading to the final refusal of the firm to dispense with the initials and numerals in the name and the consequent omission of Hexylresorcinol Solution S T 37 from New and Nonofficial Remedies. At that time the firm requested the omission of Caprokol also, stating that its continued inclusion after the exclusion of Hexylresorcinol Solution S T 37 might prove a source of misunderstanding with the Council. The Council considered this a reasonable request.

Meanwhile the firm had not submitted the new evidence required to substantiate the claims made for the product as a germicide and as a genito-urinary antiseptic. It had furthermore indicated disagreement with the Council's objection to the use of antiseptics as gargles and mouth washes. As a result of these considerations the Council voted to omit Caprokol because the claims for its therapeutic value have not been substantiated and because the manufacturer finds it impossible to handle this substance and certain of its dosage forms separately from the unacceptable dosage form Hexylresorcinol Solution S T 37.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

BAUMGARTEN'S PROCESS ALLISON COTTON-SEED FLOUR, PARTIALLY DEFATTED, COOKED

Manufacturer—The Schulenburg Oil Mill, Schulenburg, Texas

Description—Partially defatted cooked, cottonseed flour

Manufacture—Choice cottonseed is cleaned, freed from lint and hulls, passed between steel rolls, and cooked in four consecutive cookers, in each of which the mass is cooked for twenty minutes, the temperature of the fourth cooker being from 114 to 116 C. A large portion of the oil is expressed from the cooked material by hydraulic pressure. The resulting "cake" is cooled, ground fine, bolted, and packed in sacks.

Analysis (submitted by manufacturer) —

	per cent
Moisture	6.3
Ash	5.8
Fat (ether extract)	11.0
Protein (N × 6.25)	50.2
Crude fiber	3.9
Carbohydrates other than crude fiber (by difference)	22.8

Calories—39 per gram 111 per ounce

Non-toxicity—Feeding experiments with rats indicate the absence of toxicity in cottonseed flour processed according to this method.

Claims of Manufacturer—Rich in high quality protein and vitamins B and G. Free from toxic form of gossypol.

(1) STAYSWEET LIGHT CREAM (STERILIZED)

(2) STAYSWEET HEAVY CREAM (STERILIZED)

Distributor—Seggerman Nixon Corporation, New York

Packer—S M A Corporation, Cleveland

Description—(1) Canned sterile homogenized cream of 18 per cent milk-fat content. The same as Pantry Table Cream (Sterilized) (THE JOURNAL Feb 25 1933 page 576).

(2) Canned sterile homogenized cream of 36 per cent milk-fat content. The same as Pantry Whipping Cream (Sterilized) (THE JOURNAL, March 4, 1933 page 662).

Vitamins—The vitamin content may be expected to approximate that of the pasteurized cream used.

Claims of Distributor—For all table uses of cream and whipping cream respectively.

SPARKLE GELATIN DESSERT—CHERRY, LEMON, LIME, ORANGE, RASPBERRY, STRAWBERRY FLAVORS

Manufacturer—Quaker Maid Company, New York

Description—Gelatin dessert powders containing sucrose, gelatin, tartaric acid, fruit flavors (respectively terpenoid oils of orange or lemon, distilled oil of lime, and natural concentrated strawberry, raspberry or cherry flavors) and certified food colors.

Manufacture—The ingredients in formula proportions are automatically mixed, dried and packed in cartons.

STATUS THYMICOLYMPHATICUS

Few conditions have been so imperfectly understood as status thymicolymphaticus. There has been no agreement on a definition for this condition, on its essential pathologic or physiologic features, or on its etiology. The diagnosis status thymicolymphaticus or "thymic death" has far too frequently served to conceal the examiner's ignorance of the real cause of death. It has been supposed that the condition depends in some way on hyperfunction or dysfunction of the thymus. Such relationship has not been demonstrated, and evidence is lacking that the thymus is a factor in the mechanism of death in the cases so assigned. Even in the rare cases in which the thymus is so enlarged as to embarrass respiration by pressure on the trachea, death has not been shown to be the result of such obstruction. Indeed, some authors¹ relegate status thymicolymphaticus to the realm of medical mythology. The condition was recently made the subject of investigation by a special committee of the Medical Research Council and the Pathological Society of Great Britain and Ireland. The report² concludes that the facts revealed "afford no evidence that so-called 'status thymicolymphaticus' has any existence as a pathological entity."

Notwithstanding this summary dismissal, the fact remains that death occurs in certain cases from relatively trivial and apparently inadequate causes. A small percentage of apparently normal persons have an increased susceptibility to infections, intoxications, drugs, anesthetics and physical trauma. In such persons death may follow a minor infection, a slight blow, the extraction of a tooth, a trivial surgical procedure, or the administration of anesthetics, vaccines or serums. Death occurs by circulatory failure, which in some cases resembles shock. Necropsy frequently does not show an adequate cause for the death. The conditions

often found and regarded as significant are hypoplasia of the adrenals, the genitalia, the heart and great vessels, underdevelopment of secondary sex characteristics, and general lymphoid hyperplasia associated with persistence of the thymus.

Recent investigations on the function of the adrenal cortex have produced evidence which may have a bearing on so-called status thymicolymphaticus. Hyperplasia or adenoma of the adrenal cortex results in virilism and sexual precocity. There is hyperactivity of the reproductive function and prominence of secondary sex characteristics. Presumably, opposite features would result from adrenal cortical deficiency. Severe cortical deficiency results in the gradual development of circulatory failure, ending in death. Experimental cortical deficiency of sublethal degree results in weakness, low blood pressure, ease of fatigue, abnormal sensitivity to intoxications and other changes. At post mortem examination, lymphoid hyperplasia may be found. Such experiments have resulted in hyperplasia of the thymus in young animals, and in its active regeneration in older animals when partial involution of the thymus has already occurred.³ These analogies are suggestive and support the belief that this condition may be related to a dyscrasia of adrenal cortical function. The evidence is not conclusive, but it supplies a working hypothesis on which further investigations are proceeding. The newer studies may yet yield an explanation of status thymicolymphaticus.

THE ACTIVE OXYTOCIC PRINCIPLE OF ERGOT

For centuries it has been recognized that ergot possesses a property of stimulating uterine contractions. The accurate therapeutic administration of ergot, however, has been handicapped by variations in oxytocic potency of different preparations and difficulties in standardization. Much effort has been directed toward obtaining an extract or purified preparation that can be readily standardized and that possesses stability, with actions and dosage that are constant. Ergot itself is a complicated mixture, but in the past the active principle has generally been believed to rest in the alkaloidal constituents.

Recently workers in the United States and in England have reported almost simultaneously derivatives of ergot that they respectively believe are the most refined and active ones yet described. In February 1935 an article by a group of Chicago workers¹ appeared in which they state that their preparation "contains all the oxytocic principles (alkaloidal as well as nonalkaloidal)" and say that it is "the crude extract

but in reality, it is a very fine, almost crystalline powder. It is completely soluble in alcohol and all hydrophilic solvents. It has no unpleasant properties characteristic of the fluidextract of ergot. This preparation was dissolved in alcohol and administered as such or given in the form of a capsule. The total amount of the drug administered in each instance was the residue from a 3 Gm sample of the crude drug.² By the colorimetric test or the precipitant reagent the total alkaloidal content per dose is less than 1/100,000. A note at the end of this communication states that since the work was reported it has been possible to isolate the pure active principle in crystalline form, which has been found therapeutically active in doses of 0.1 mg in the postpartum patient. This statement, coming at the end of the report, naturally gives rise³ to the supposition that the studies reported were made with a product less pure than the ultimate crystalline substance. The Chicago workers have, however, conducted investigations with the pure crystalline "ergotocin" on more than 200 patients.⁴

The most satisfactory method of assay for this principle was found to be on the human postpartum uterus by a method previously described⁴ and on the postpartum uterus of the dog. With this method it was possible to make accurate determinations of the oxytocic effect.

In March, an article by Dudley and Moir⁵ appeared on the same subject. They reported the isolation of 0.82 Gm of crystals from 10 Kg of defatted ergot. In clinical trial, by a method on the postpartum human uterus, this crystalline substance was found actively oxytocic. An adequate dose for intramuscular administration appeared to be from 0.25 to 0.5 mg, which produces strong uterine contractions in from three and one-half to four and one-half minutes.

There seems no question that the work of the two groups was done entirely independently. The chemical and physiologic identity of the two substances is not a matter of equal certainty. In the derivative obtained by the Chicago investigators,⁶ from 3 to 4 Gm of crude defatted ergot yields 0.3 mg of the purified substance, which they have named "ergotocin."⁷ The British workers obtained a roughly equal portion of their crystalline product (approximately 0.8 mg per gram of crude defatted ergot). A satisfactory chemical comparison of the two substances is not yet possible on the basis of published statements. It is necessary to point out, however, that the British workers report a specific rotation of $[\alpha]_D$ of the material recrystallized from benzene — 45°. The Americans⁶ state that "the optical rotation of the salts of 'ergotocin' so far inves-

tigated is positive." On this basis there is no reason to conclude that the two substances are chemically identical.

Whatever the ultimate outcome, it is certain that one or more crystalline derivatives of ergot have now been prepared. The method of assay on the human postpartum uterus is relatively satisfactory and in all probability a more active and stable substance will soon be available for clinical administration.

HORMONES AND BLOOD LIPIDS

A vast amount of experimental investigation during the last few years has demonstrated that the quantity of body fat may be significantly influenced by the secretions of certain endocrine glands. The effects on fat metabolism of the hormones thyroxine, insulin and some substance present in the pituitary are well known. Recently,¹ the relation of insulin and of posterior pituitary extract to lipid metabolism has been studied by a method in which the results of fat tolerance tests were compared in thin and obese subjects treated with and without insulin or pituitary extract. The patients were given a fat test meal consisting of 100 Gm of fat in the form of 500 cc of 20 per cent cream. The plasma cholesterol was then determined on the alternate hours as an indicator of the level of blood lipid, since the quantity of cholesterol in plasma varies fairly consistently with the total amount of blood fat. In normal subjects the plasma cholesterol level remained practically unaltered after the ingestion of the test meal. Similar results were obtained in the untreated thin subjects. When, however, these patients were given insulin, the plasma cholesterol curves were strikingly different, the cholesterol value rose sharply and remained elevated for several hours.

The cholesterol curves obtained in the untreated obese subjects differed markedly from those in the untreated normal and thin individuals. The plasma cholesterol usually showed a prompt rise after the ingestion of the fat meal and remained high for several hours, just as was the case in the insulin-treated, thin patients. When posterior pituitary extract (solution of pituitary, U S P) was given either intranasally or intramuscularly to obese patients, the usual increase in plasma cholesterol did not occur. The value remained virtually unaltered for as long as eight hours. Further data indicating a similar relation between blood lipids and the pituitary were obtained in a group of patients with diabetes insipidus. Following the ingestion of the test meal there was a marked rise in plasma cholesterol, and the level remained high during the entire eight hour period. Also, as in the case of the treated obese subjects, the administration of posterior pituitary extract prevented the rise in the plasma lipid. The foregoing data clearly indicate that the preparations in

question may exert a profound regulatory effect on fat metabolism, insulin promoting an increase in the blood lipid whereas the posterior pituitary extract exerts an inhibitory action

The possibility that insulin and pituitary extract may be of clinical value in the control of body fat is of immediate interest. At the present time there is considerable evidence² that the administration of insulin to thin individuals promotes an increase in body weight. The effect of posterior pituitary extract in reducing body weight is now under investigation.¹ Preliminary studies with six obese patients have shown that the administration of the pituitary preparation intranasally, three times a day, promoted an average weekly loss of from 1½ to 2 pounds. These data are of course too few to permit conclusions regarding the efficacy of posterior pituitary extract in the treatment of obesity. It is necessary to keep in mind the many physiologic changes produced by extracts of the posterior lobe of the pituitary in employing such products clinically. As Geiling³ has pointed out in the series on glandular physiology and therapy now appearing in *THE JOURNAL*, striking effects are produced on the cardiovascular and respiratory systems on the gastro-intestinal tract and on metabolism in addition to the well known oxytocic action. Thus harmful results might readily obtain from the ill considered use of posterior pituitary extracts, particularly in certain disease states, for instance those involving the circulatory system. Much more work needs to be done under carefully controlled conditions before the indications and contraindications to the employment of these preparations in the treatment of obesity are known. Routine clinical applications are not yet warranted.

ROSENWALD FUND ANNOUNCES PLAN FOR SOCIALIZATION

The following item from the *Chicago Tribune* of May 20 indicates the plans of the Rosenwald Fund for the coming year:

Trustees of the Julius Rosenwald fund voted yesterday an appropriation of \$284,000 to be expended in the fiscal year beginning July 1 for welfare work and rural education among colored persons, and for furthering socialized medicine. Edwin R. Embree, president of the fund, said that the Rosenwald effort to place competent medical service and hospitalization within the reach of persons of moderate means paralleled the program of the medical profession. He quoted Dr. Michael M. Davis of the fund's medical division as reporting that 344 plans to cut the cost of medical care, or to make it easier for the average family to pay for it, had come to his office in the last year. Certain of these projects he said had been endorsed in principle by the American College of Surgeons.

The medical profession should be aware of this propaganda in behalf of state medicine. In the crystallization of public opinion, physicians will do well to bring the point of view of the medical profession to the attention of their patients, women's clubs, Rotary clubs, Kiwanis clubs, chambers of commerce and similar organizations.

PNEUMOCONIOSIS

The Bureau of Mines¹ has recently issued a statement reviewing the literature on the effects of breathing dusts, especially silica dusts. Two further reports dealing with prevention and treatment of dust diseases and some of their economic and legal aspects in industry are to appear later. The material in the report is extensive and few general conclusions are drawn. It is fairly safe to infer, however, that the silicotic lung is more susceptible to bacterial infection than the average lung. This is probably due to the irritation of the respiratory tissues by the inhaled dust particles, which weakens the mucous membranes and renders them susceptible to infection. The toxic influence of certain inorganic dusts on the tissues may be a contributing factor. There are almost as many classifications of stages of silicosis as there are studies of the subject. Thus, the Committee on Standard Practices in Compensation of Occupational Diseases of the American Public Health Association describe three arbitrarily divided stages. Pancoast and Pendergrass suggest the following: (1) peribronchial-perivascular-lymph node predominance type, (2) early interstitial predominance, (3) advanced interstitial predominance, (4) nodular predominance and (5) advanced diffuse or terminal fibrosis. A detailed statement of occupation is important in diagnosis. The mere fact that a man is a miner has slight, if any, value. The cardinal physical observation in silicosis is diminished chest expansion. It is generally accepted, however, that the roentgenogram offers the best and most reliable indication of the lung changes that occur in silicosis, particularly in the early stage. Finally it was agreed at the International Congress on Silicosis in 1930 that, to produce the pathologic condition, silica must reach the lungs (1) in a chemically uncombined condition, although the dust inhaled may be either a natural mixture of silicon dioxide with other dusts, such as occurs in granite, or an artificial mixture, such as scouring powder, (2) in fine particles of less than 10 microns in diameter, and (3) in sufficient amount and over a certain period of time, the latter two factors being reciprocal variants. The minimum of these two factors has not yet been determined.

¹ Harrington, D. and Davenport, Sara J. Review of Literature on Effects of Breathing Dusts, with Especial Reference to Silicosis. Information Circular 6835. Department of Interior. Bureau of Mines.

Animal and Vegetable Proteins—Animal proteins usually contain a more satisfactory assortment of amino acids than those of vegetable origin. The much vaunted gelatin is, however, a glaring exception, since it is devoid of tryptophan and contains at most a trace of tyrosine and cystine. Since none of these amino acids can be formed in the animal's body, gelatin affords a mixture of amino acids that is wholly inadequate.—Newburgh, L. H., and MacKinnon, Frances. *The Practice of Dietetics*. New York: Macmillan Company, 1934.

Association News

THE ATLANTIC CITY SESSION

Hotel Reservations for Members of the House of Delegates

Tentative reservations for all members of the House of Delegates of the American Medical Association have been made at the Ambassador Hotel in Atlantic City, and each delegate whose name has been made known to the Secretary of the American Medical Association has received a letter concerning this matter. It appears that a number of delegates have not yet made their final reservations. It is important that each member of the House of Delegates who wishes to have accommodations at the Ambassador Hotel should write at once to the hotel management stating the kind of accommodations desired and the time of expected arrival in Atlantic City.

Dinner of Section on Gastro-Enterology and Proctology

The Section on Gastro-Enterology and Proctology of the American Medical Association will hold its annual dinner at the Hotel Shelburne in Atlantic City Thursday evening, June 13, at 6:30. The cost of the dinner will be \$2.50, and tickets may be procured during the meetings of the section Wednesday and Thursday afternoons.

Annual Dinner of Medical Veterans

The dinner of the Medical Veterans of the World War will be held at 7 p. m., Wednesday, June 12, at Kornblaus, Atlantic City. The charge will be \$2.50 per plate. Tickets will be on sale at the Central Information and Ticket Bureau of the American Medical Association beginning June 10. Groups desiring to make reservations prior to that date should communicate with the president of the section, Major Albert G. Hulett, 20 Hawthorne Avenue, East Orange, N. J., or the chairman of the local committee of arrangements, Lieut. Comdr. David Allman, 104 St. Charles Place, Atlantic City.

Change in Date for Luncheon

The Phi Delta Epsilon Fraternity luncheon will be held Thursday, June 13 at 12:30 p. m. at the Ambassador Hotel, Atlantic City. The luncheon had previously been announced for Tuesday, June 11.

Chicago Medical Society Special Train

Dr. Thomas P. Foley, secretary of the Chicago Medical Society, 185 North Wabash Avenue, Chicago, announces that an air conditioned special train to be known as the Chicago Medical Society Special, will be operated over the Pennsylvania Railroad from Chicago to Atlantic City. This train will leave the Chicago Union Station at 12 noon central standard time, June 9, will leave Fort Wayne Ind. 2:57 p. m. central standard time, June 9 and will arrive in Atlantic City at 9:15 a. m. eastern standard time, June 10.

The Chicago Medical Society extends an invitation to members of the American Medical Association who are going to Atlantic City to join the Chicago party on this special train. For the trip from Chicago to Atlantic City no extra fare will be charged.

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45 Chicago daylight saving time (3:30 central standard time). The next two broadcasts will be delivered by Dr. W. W. Bauer. The titles will be as follows:

May 30 Holiday no broadcast
June 6 Wound Infections
June 13 Summer Camps

National Broadcasting Company

The American Medical Association broadcasts under the title Your Health on a Blue network of the National Broadcasting

Company each Tuesday afternoon from 4 to 4:15, Chicago daylight saving time (3 o'clock central standard time). The next three broadcasts will be as follows:

May 28 Health Frontiers W. W. Bauer, M.D.
June 4 The Crippled Child W. W. Bauer, M.D.
June 11 From Philadelphia speaker and topic to be announced

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Bills Introduced—H. 360 proposes to grant to physicians and surgeons attending a person during his last illness liens on the proceeds of any policy of insurance on the patient's life, regardless of who may be the named beneficiary of such insurance. H. 368 to amend the workmen's compensation act, proposes, among other things, to require an employer to furnish medical and surgical treatment to a worker disabled in an industrial accident, during the first ninety days (rather than sixty days) of disability and to raise the employer's liability for such services to \$300, rather than \$100 as the present law provides.

CALIFORNIA

Bill Introduced—A. 2441 proposes to prohibit the sale of dinitrophenol or thyroid and compounds, preparations or derivatives thereof, including all such substances as are or may hereafter be trademarked, patented or copyrighted and proprietary medicines, except on the written prescription of a licensed physician or "osteopathic physician duly licensed under the state medical practice act."

Compulsory Health Insurance Is Dead—According to the San Francisco *Examiner*, May 18, the issue of compulsory public health insurance in California is dead, at least until 1937, as far as the state legislature is concerned. On petition of thirty-eight of the forty members of the senate, a resolution was passed, May 17, to create an interim committee to study further the question of health insurance and to report at the 1937 session. On this committee have been appointed Senators Tickle, Williams, Difani, Pierovich and Knowland, the first three of whom were members of the 1933-1935 committee, which filed an exhaustive report on health insurance. The new committee will be empowered to accept donations from private sources to continue the inquiry, but the bill introduced in the senate creating a state organization to carry on for health insurance will not be pressed.

FLORIDA

Annual Short Course—The third annual short course for physicians will be conducted at the University of Florida, June 24-29, under the auspices of the general extension division and the Florida Medical Association. Included among those directing the course will be:

Dr. Fred L. Adair, Chicago, professor of obstetrics and gynecology, University of Chicago
Dr. Oscar W. Bethea, New Orleans, professor of clinical medicine, Tulane University of Louisiana School of Medicine
Dr. Horton R. Casparis, Nashville, professor of pediatrics, Vanderbilt University School of Medicine
Dr. Emil Novak, Baltimore, associate professor of obstetrics, University of Maryland School of Medicine
Dr. Willis C. Campbell, Memphis, professor of orthopedic surgery, University of Tennessee School of Medicine
Dr. Arthur M. Shipley, Baltimore, professor of surgery, University of Maryland School of Medicine, and associate professor of surgery, Johns Hopkins University School of Medicine
Dr. Oliver C. Wenger, Hot Springs, National Park, surgeon, U. S. Public Health Service

ILLINOIS

Motor Accidents Increase—The state health department announces a total of 2,572 deaths from motor vehicle accidents in 1934, the highest annual number in the history of the state. The mortality rate was 32.6 per thousand of population as compared with 29.5 in 1930, the previous high record. Collision with other motor vehicles and with fixed objects such as telephone poles and bridge abutments accounted for the great-

est proportionate increases in fatal accidents last year. The department reports that running down pedestrians accounted for almost half the fatal accidents, a total of 1,249.

Chicago

Personal—Floyd S. Markham and Sion W. Holley, students in the Division of Biological Sciences, University of Chicago, have been awarded the Howard Taylor Ricketts Prize, which is given annually for the best results in research in either pathology or hygiene and bacteriology.

Rockefeller Gift to Psychiatry Department—The University of Chicago has received a gift of \$243,000 from the Rockefeller Foundation of which \$168,000 will be used to establish a department of psychiatry in the medical school for research into the causes and cure of mental diseases. It is planned to open the new department July 1. The remaining \$75,000 will be used to aid the university's research in the humanities.

INDIANA

Chiropractors' Health Certificates Not Acceptable—City health officers are not required to accept health certificates signed by chiropractors according to an opinion handed down by the attorney general of Indiana recently. The opinion was written in connection with the recent refusal of Dr. Herschel G. Cole Hammond to accept certificates signed by Holloway Ford, a chiropractor. Dr. Cole, secretary of the health board of Hammond, refused to accept two certificates attesting the health of two persons asking permission to handle food, according to the *Journal of the Indiana State Medical Association*. The opinion points out that a licensed chiropractor is limited to practice in his profession, as a drugless physician and that a health certificate, to be recognized as such, should bear the signature of one authorized to diagnose human ills generally.

Annual Graduate Meeting—The fourth annual graduate educational meeting of the Indiana State Medical Association was a joint session with the First District Medical Society at the Elks Home, Evansville, May 8. Speakers on the program included:

Rolla N. Harger, Ph.D., Indianapolis: New Developments in Vitamins.
Dr. Ernest O. Asher, New Augusta: Obstetrics in the Home.
Dr. Paul D. Cramm, Evansville: Newer Methods in Diagnosis and Treatment of Pulmonary Tuberculosis.
Dr. Everett E. Padgett, Indianapolis: Diagnosis and Surgical Management of Gallbladder Disease.
Dr. Clyde G. Culbertson, Indianapolis: Role of the Clinical Pathologist as a Consultant to the General Practitioner.
Dr. Maurice V. Kahler, Indianapolis: Female Sex Hormones.
Dr. Beaumont S. Cornell, Fort Wayne: Diseases of the Colon.
Dr. Nelson K. Forster, Hammond: Emergency Surgical Treatment.
Dr. John H. Warvel, Indianapolis: Diabetes.
Dr. Roscoe L. Senesich, South Bend: The Medical Economic Picture Up-to-Date.
Dr. Louis H. Segar, Indianapolis: Common Sense in the Care of Children.

MARYLAND

State Society Benefits by Physician's Will—The Medical and Surgical Faculty of the State of Maryland will eventually receive the bulk of the estate of Dr. John Ruhräh, according to the terms of his will, it is reported. The faculty may have immediately whatever books it desires from the physician's library but will receive the remainder of the legacy on the death of Dr. Ruhräh's survivors. When this takes place, the Ruhräh Fund for the Benefit of the Library will be created, its use to be governed by provisions in the will.

Conference of Health Officers and Boards of Health—The fifteenth annual conference of health officers and boards of health of Maryland will be held at Johns Hopkins University School of Hygiene and Public Health, May 31-June 1. The tentative program includes the following speakers:

Dr. Reginald M. Atwater, executive secretary American Public Health Association, Team Work in the County Health Unit.
Dr. Henry D. Chadwick, commissioner of health of Massachusetts: Tuberculosis Program in Massachusetts.
Dr. Stanley H. Osborn, commissioner of health of Connecticut: Occupational Diseases.
Dr. George C. Ruhland, commissioner of health of the District of Columbia: Measles Control.
Dr. William A. McIntosh, Rockefeller Foundation: New York General Policies in the Field of County Health Administration.

The governor of Maryland, Harry W. Nice, will be on the program.

MASSACHUSETTS

Hospital News—The Forest Hills Hospital recently opened an outpatient department with Dr. Alonzo J. Shadman as managing director. Dr. Archibald McK. Fraser has been appointed surgeon in chief of the first surgical service, and Dr. Howard M. Clute, of the second surgical service at Carney Hospital, Boston. Dr. Fred B. Lund, surgeon in chief for the past

nine years, is now consulting surgeon.—The Hospital Council of Boston was recently organized with Dr. Joseph B. Howland, superintendent of Peter Bent Brigham Hospital, as president, and Dr. Charles F. Wilinsky, superintendent of Beth Israel Hospital, secretary. Twenty-four hospitals are members.

Dr. Mallory Receives the Gold Headed Cane—At the annual meeting of the American Association of Pathologists and Bacteriologists, April 17, it was voted to confer a gold headed cane on Dr. Frank Burr Mallory, emeritus professor of pathology, Harvard Medical School, Boston. Before his death in 1922, Dr. Harold C. Ernst, who had for years been secretary of the association, turned over to it this cane to serve as a symbol of tribute by the association to distinguished pathologists. According to Dr. Howard T. Karsner, Cleveland, now secretary of the organization, the cane has been held by Drs. William H. Welch and Theobald Smith.

MICHIGAN

Personal—Dr. Robert G. White, Detroit, has been appointed school physician in Ann Arbor, succeeding Dr. Earl E. Kleinschmidt, resigned after three years service.—Dr. Wellington B. Huntley, Hudson, has been appointed head of the medical staff of the Michigan State Prison Hospital, Jackson, succeeding Dr. John W. Speck.—Dr. Francis A. Hargrave, who has completed fifty years in practice in Palo Alto, was recently honored at dinner in recognition of his seventy-eighth birthday.

Health Council Created—The Health Council of Metropolitan Detroit has been organized with Dr. Hugo A. Freund as permanent chairman. The council, which was unanimously endorsed at a meeting of the Wayne County Medical Society in December (*THE JOURNAL*, February 9, p. 482), held its first meeting, April 4. The twenty-four members of the council are representatives of the various health agencies in the city. It proposes to procure health service for all the people at a minimum of expense and will seek to reach a common ground of understanding between medical and social groups devoted to the care of the sick as well as to harmonize views of all groups interested in health problems.

NEBRASKA

Hospital Anniversary Clinics—The Lincoln General Hospital celebrated its tenth anniversary in April with a two day program of clinics attended by about 250 physicians. Guest speakers and clinicians were Drs. John H. Musser, New Orleans, who held a medical clinic; Fred H. Albee, New York, who spoke on surgery of the bones and joints; Noble Sproat Heaney, Chicago, obstetric conditions; and Gioacchino Failla, Sc.D., New York, therapeutic use of high voltage roentgen rays.

Society News—Dr. Albert C. Furstenberg, Ann Arbor, Mich., addressed the Omaha-Douglas County Medical Society, April 17, on "Acute Infections of the Face and Neck."—Dr. Edward C. Rosenow, Rochester, Minn., addressed the Lincoln District Medical Society and the Lancaster County Medical Society, March 4, on infections centralized in the nose, throat and teeth.—A symposium on anemias was a part of the program of the Third Councilor District Medical Society at Falls City, April 18, presented by Drs. James P. Tollman, Archibald R. McIntyre, Howard B. Hamilton and John B. Potts, all of the faculty of the University of Nebraska College of Medicine, Omaha.—Drs. Arthur E. Hertzler and George A. Westfall, Halstead, Kan., addressed the Southwestern Nebraska Medical Society, McCook, April 11, on gastroduodenal ulcers and other gastro-enterologic subjects.

NEW HAMPSHIRE

State Medical Election—Officers elected at the recent annual meeting of the New Hampshire Medical Society are: Drs. Clifton S. Abbott, Laconia, president; Frank E. Kittredge, Nashua, vice president; and Carleton R. Metcalf, Concord, secretary-treasurer. The next annual meeting of the association will be held in Manchester, May 12-13, 1936.

NEW YORK

Dr. Fronczak Honored—Dr. Francis E. Fronczak, Buffalo, was honored at a reception given by friends and associates at the Lafayette Hotel, March 27, on his completion of twenty five years as health commissioner of the city. Polish-American citizens presented to him a brief case and his fellow workers a watch. Dr. Fronczak is a native of Buffalo and a graduate of the University of Buffalo School of Medicine, class of 1897. He entered the department of health in 1907 as assistant commissioner and was made commissioner in 1910. During the World War he served overseas and was decorated by Poland.

with the Order of Polonia Restituta and the Cross of Valor of Poland for his service with the army and as a member of a relief mission. He also received the cross of the Legion of Honor of France.

Health at Albany—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended May 11, indicate that the highest mortality rate (21.3) appears for Albany and for the group of cities as a whole, 12. The mortality rate for the corresponding period last year was 11.9 for Albany and 11.8 for the group of cities. The annual rate for eighty-six cities for the nineteen weeks of 1935 was 12.6 as against a rate of 12.5 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

New York City

League to Abate Noise—With the organization of the League for Less Noise, May 16, the efforts of several agencies in New York will be coordinated to reduce the noise of the city. The new league includes the recently formed League for Noise Abatement and will have its headquarters at 580 Fifth Avenue. Included among the representatives of civic, business and science leaders at the meeting were those of the police and health departments and the New York Academy of Medicine. E. H. Peabody, president of the Peabody Engineering Corporation, who was chairman of the conference meeting, was unanimously elected president. Speakers at the meeting included Drs. Shirley Wynne, former health commissioner, E. H. Lewinski Corwin, Ph.D., and John Oberwager.

Public Exhibit of Cancer Facilities—The New York City Cancer Committee sponsored an exhibit to show the facilities available in New York for the diagnosis and treatment of cancer and for the care of the needy cancer patient, at the Hotel Plaza, May 14-20. A number of hospitals participated, including Bellevue Hospital and the division of cancer of the department of hospitals, Lenox Hill, Mount Sinai, Montefiore, New York, Presbyterian, Roosevelt, Fifth Avenue, St. Vincent's, Sloane, Woman's and St. Luke's hospitals, Memorial Hospital for Treatment of Cancer and Allied Diseases, and New York Skin and Cancer Unit of New York Post-Graduate Hospital. Various organizations for cancer control and several social agencies also took part. At a luncheon at the Plaza May 15, Prof. Stephen Leacock, McGill University, Montreal, spoke on 'The Conquest of Disease', Dr. John A. Hartwell, "How New York Is Meeting the Cancer Problem," and Mr. W. Kingsland Macy, "The Lay Person's Share in the Cancer Campaign."

New Regulations for Private Hospitals—The department of hospitals of New York issued new regulations to provide stricter control of private hospitals and sanatoriums, April 22, following a study made jointly by the department and the coordinating committee of the five county medical societies. Under the new rules each proprietary hospital must be supervised by a medical board including an internist, a surgeon, an obstetrician if maternity service is offered, and a pathologist. This board is to make yearly inspections and is to be responsible for the maintenance of proper professional and ethical standards. Each hospital must have a resident physician, and at least one graduate nurse must be present at all times. Payment of commissions, bonuses or gratuities in any form to any physician or to any organization directly or indirectly is forbidden. All hospitals must be licensed for a definite number of beds and, if the number is changed, an amended application must be filed. Other rules concern compliance with fire and sanitary laws, isolation rooms for communicable diseases, laboratories for all hospitals with capacities over thirty beds, x-ray apparatus and annual statistical reports. The department will not recognize as hospitals any establishments occupying sections of hotel or multiple dwellings.

OHIO

Bill Introduced—S. 344 proposes to levy a tax of 3 per cent on charges made for professional services. The bill proposes that "the tax hereby imposed shall apply and be collected when the service is rendered, regardless of the time when the agreement therefor is made, or when the price is paid or delivered."

Executive Secretary Appointed—Mr. Charles Nelson since 1928 assistant to Don K. Martin as executive secretary of the Ohio State Medical Association, has been made executive secretary to succeed Mr. Martin. Mr. Nelson is a native

of Marion and was engaged in newspaper work before he entered the office of the state society. Mr. Martin resigned recently to become executive secretary of the Ohio Manufacturers Association.

Society News—At a meeting of the Hempstead Academy of Medicine at Portsmouth, April 8, Dr. Gordon F. McKim, Cincinnati, spoke on "Differential Diagnosis of Prostatic Conditions."—Weston A. Price, D.D.S., Cleveland, addressed a combined meeting of the Columbus Academy of Medicine and the Columbus Dental Society, April 15, on "Studies Among Primitive Races for Light on Why Modern Civilization Hastens Physical Degeneration."—Four Detroit physicians presented the following program of the Summit County Medical Society, Akron, at its meeting May 15: Drs. Frederick L. Sperry, "Chronic Irritable Colon"; John A. Maloney, "Psychogenic Concepts of Migraine"; Silas W. Wallace, "Focal Infections in Relation to Systemic Diseases"; Complement Fixation as a Diagnostic Aid; and Howard C. Walser, "Asphyxia Neonatorum."—The Union Medical Association of the sixth councilor district met in Canton, April 10, with addresses on acute conditions of the ear, nose and throat presented by Drs. James R. Dowling, Massillon, James E. Springer, Akron, George L. King, Alliance, William H. Evans, Youngstown, John N. Hoffmann, Canton, and Edward W. Douglas, Wooster.—At a meeting of the Adams County Medical Society, West Union, April 17, Dr. Clifford G. Foor, Hillsboro, discussed diseases of the stomach and duodenum and Dr. Samuel C. Clark, Cherry Fork, mumps.—Dr. Louis J. Karnosh, Cleveland, addressed the Lorain County Medical Society, April 9, on "The History of Neuropsychiatry."—Dr. Kenneth F. Lowry, Troy, addressed the Miami County Medical Society, Piqua, April 5, on "Postoperative Care of Surgical Patients."—Dr. Stanley S. Sidenberg, Cleveland, addressed the Marion Academy of Medicine, Marion, on treatment of tuberculosis by pneumothorax.—Dr. Thomas R. Brown, Baltimore, delivered the annual Alpha Omega Alpha lecture of the Cincinnati Academy of Medicine, May 20, on "Problems in the Digestive Field."

OREGON

Fiftieth Anniversary—The Multnomah County Medical Society entertained Dr. and Mrs. Edward Allen Pierce, Portland, at dinner at the Multnomah Hotel, April 15, to celebrate Dr. Pierce's fiftieth anniversary in the practice of medicine. Dr. Pierce was president of the Oregon State Medical Society in 1909-1910 and was a member of the state board of health for many years.

Society News—Drs. Richard F. Berg and Thomas D. Robertson, Portland, addressed the Multnomah County Medical Society, April 3, on pathology of the knee joint and examples of clinicopathologic correlation. Speakers April 17 were Drs. Merle W. Moore, on "Points to Consider in Diagnosis of Gastro-Intestinal Allergy," and Warren C. Hunter, "Clinical and Pathologic Correlation of Dissecting Aortic Aneurysm."

PENNSYLVANIA

Cancer Meeting at Meadville—The Cancer Commission of the Medical Society of the State of Pennsylvania held its annual western sectional meeting at Meadville, May 15. Dr. George E. Pfahler, Philadelphia, chairman of the commission, made an address on "Diagnosis and Treatment of Cancer of the Bladder by Means of X-Rays" and the following New York physicians spoke: Drs. Ralph E. Herendeen, "Treatment of Bone Tumors"; Hayes E. Martin, "Diagnosis and Treatment of Intraoral Cancer," and Frank E. Adair, "Diagnosis and Treatment of Breast Lesions." Dr. Harry C. Winslow, Meadville, was chairman.

Philadelphia

Society News—The Philadelphia County Medical Society presented a program on cancer, April 24, with the following speakers: Drs. Frank E. Adair, New York, on "The Attitude of the Modern Surgeon Toward Cancer Therapy"; George P. Muller, "Diagnosis of Tumors Within the Chest"; Thomas Grier Miller, "Nonspecific Management of the Cancer Patient," and Stanley P. Reimann, "Current Events in Cancer Research."

Seminars on Infections—The current series of graduate seminars presented by the Philadelphia County Medical Society on Friday afternoons is made up of the following:

- May 10: Drs. Frank B. Lynch, Jr., Pneumonia from the Laboratory Angle; Hobart A. Reimann, Minneapolis from the Clinical Angle.
- May 17: Dr. William Bates, Minor Surgical Infections as Seen in the Office of the General Practitioner.
- May 24: Drs. William P. Belk, Ardmore, Pa., Infections of the Kidney and Prostate from the Laboratory Angle; Leon Herman from the Clinical Angle.
- May 31: Dr. Clifford B. Lull, Infections of the Cervix as Seen in the Office of the General Practitioner.

RHODE ISLAND

Society News—Dr Walter C H Weigner, Providence, addressed the Washington County Medical Society, Westerly, April 10, on "Functional Factors in Disease"—Dr Gilbert Horrax, Boston, made an address at the State Hospital for Mental Diseases, Howard, March 19, on "Neurosurgical Conditions of Interest to Psychiatrists"—The Providence Medical Association held a joint meeting with the New England Pediatric Society, May 6, at which the following papers were presented: Drs Dennett L Richardson, "Immunization Against Measles", Maurice Adelman, "Purpura as a Complication of Scarlet Fever," and Murry S Danforth, "Review of Cases of Legg-Calve Perthes Disease"

SOUTH DAKOTA

Personal—Dr Raymond P Frink, Wagner has been appointed agency physician for the Yankton Indian Reservation, as successor to Dr Andrew Rittan—Dr August E Bostrom, De Smet, has resumed private practice after several years as epidemiologist of the state board of health and more recently with the Indian Medical Service.—Dr Emil G Erickson has been appointed health officer of Sioux Falls—Dr Burt A Dyar, De Smet, has been appointed by the state relief administration to make a survey of tuberculosis and other contagious diseases among the adult indigent

State Society's Radio Program—Since December 1934 the South Dakota State Medical Association has sponsored a radio program Sunday evenings from 6:45 to 7 o'clock over Station WNAX, Yankton. District societies are responsible for a month's broadcast in turn. A committee of the state association with the following members is in charge of the general plan: Drs Silas M Holif, Yankton, Edward W Jones, Mitchell, Edwin L Perkins, Sioux Falls, and John F D Cook, Langford, secretary of the state association. This committee passes on all papers, requiring that they be submitted sixty days before the broadcast date. In addition, there is an editorial board consisting of the councilor president and secretary of each district. Mimeographed copies of the papers may be obtained from Dr Cook. Dr Robert A Buchanan, Huron broadcast, May 19 on Breast Feeding in Infants

WASHINGTON

Personal—Dr Lunsford D Fricks, for the past eight years district director in Seattle for the U S Public Health Service was transferred to Honolulu as chief quarantine officer, March 1

Society News—Dr Maurice F Dwyer addressed the King County Medical Society, Seattle, May 6 on cancer of the uterus—Drs John F LeCocq and Glenn N Rotton, Seattle addressed the Chelan County Medical Society, April 3 on "Perthes Disease and Allied Conditions and Breech Delivery," respectively—Dr Albert J Bowles, Seattle, addressed a joint meeting of the Skagit County Medical Society and the Mount Baker District Dental Society, Mount Vernon, April 2, on "Hypoparathyroidism and Calcium Metabolism"

WISCONSIN

Bills Introduced—S 401 proposes to authorize the establishment in Madison of a hospital for the observation, diagnosis and treatment of the sick, and particularly of persons afflicted with mental diseases, to be operated in connection with and under the direction and supervision of the medical department of the University of Wisconsin. The bill also proposes that every physician on the staff of any county hospital for the insane is to devote at least two weeks in each year to psychiatry work in this hospital. A 948 proposes that "any one practicing chiropractic who shall fail to perform or who shall negligently or unskillfully perform or attempt to perform any duty assumed which is ordinarily performed by authorized practitioners shall be liable to the penalties and liabilities for malpractice." A 909 proposes to provide that an injured person having a claim or a right of action on account of his injuries may assign to the hospital treating him such part of any recovery had or to which he is entitled, sufficient in amount to cover the cost of his hospital care. A 933 proposes to require a physician who has attended or examined an injured workman at the request of the employer or of his insurance carrier to give to the worker or if he is deceased to his personal representative, a copy of each report he makes to the employer or insurance carrier. However in cases in which the giving of such a report to the worker would be deemed inimical to the interests of the employer, a copy of the report must be filed with the industrial commission. If any physician fails to make the reports required by this bill his testimony is not to be received in evidence by the industrial commission.

GENERAL

Medical Bills in Congress—Changes in Status S 2472 has been reported to the Senate, proposing to authorize an annuity to Frances Agramonte, the widow of Dr Aristides Agramonte, member of the yellow fever commission, H J Res 249 has passed the House, providing for participation by the United States in the Eighth International Congress of Military Medicine and Pharmacy to be held at Brussels, Belgium in 1935

Society News—The annual meeting of the American Association of Industrial Physicians and Surgeons will be held in Philadelphia, June 10-11, at the Hotel Pennsylvania.—The American Nisserian Medical Society will meet in annual session at the Claridge Hotel, Atlantic City, June 11.—The University of Minnesota and Mayo Foundation Alumni dinner will be held at the Ambassador Hotel, June 12.—The Society of Plastic and Reconstructive Surgery will meet in Atlantic City at the Chalfonte-Haddon Hall Hotel, June 14-15

Changes in Status of Licensure—At a meeting of the California Board of Medical Examiners recently, the following action was taken:

Dr Horsep Hagop Mahdessian, Fresno, placed on probation for two years without narcotic privileges or possession

Dr Edward Peter Genocchio, San Francisco, found guilty of violation of the terms of the medical practice act concerning advertising was placed on probation for three years

The North Carolina Board of Medical Examiners recently reported the following:

Dr John Harvey Hudson, Greenville, license restored Dec. 3, 1934, it was revoked July 15, 1929

National Tuberculosis Association—The thirty first annual meeting of the National Tuberculosis Association will be held in Saranac Lake, N Y, June 24-27, under the presidency of Dr Henry Kennon Dunham, Cincinnati. The preliminary program announces, among other features, a group of papers on pneumothorax treatment to be presented by Drs. John Alexander, Ann Arbor, Mich., Richard H Morgan, Detroit, Hugh B Campbell, Norwich, Conn., George C Turner, Chicago, Dean B Cole and Edgar C Harper, Richmond, Va., and Philip B Matz, Washington D C. At the opening general meeting there will be special tributes to Dr Edward L Trudeau, founder of Saranac Lake Sanitarium fifty years ago, presented by Drs Allen K Krause, Tucson, Ariz., Charles C Trembley, Saranac Lake, N Y, and Harry A Pattison, Livingston, N Y

Broadcasting Company Prohibits Certain Advertising Programs—The Columbia Broadcasting System has announced certain new policies which among other things will exclude the advertising of laxatives, deodorants and depilatories. Restrictions have also been placed on the amount of advertising on the air, effective July 30. After 6 p m the advertising will be held to 10 per cent of the total scheduled time while the day time programs will be restricted to 15 per cent. The new rules provide that no new laxative or other products "describing graphically or repellently any internal bodily function or matters not generally acceptable topics in social groups" will be accepted and that accounts in this category will all be removed from the air by March 1, 1936. Contracts of this type expiring in the meantime will not be renewed. The Columbia Broadcasting System is engaging the services of an "eminent child psychologist, who will have the benefit of an advisory board of qualified members with the special purpose of pointing the way toward programs designed to meet the approval of parents, children and educators."

Winners in Health Conservation Contests—The United States Chamber of Commerce at its annual meeting in Washington, D C, April 29, announced the winners in the sixth annual city and the first rural health conservation contests. For the second consecutive year Baltimore was the winner in the class of cities with populations over 500,000. In the five other population groups winners were: between 250,000 and 500,000, Newark, N J, between 100,000 and 250,000, Honolulu, Hawaii, between 50,000 and 100,000, Pasadena, Calif., between 20,000 and 50,000, Hackensack, N J, and under 20,000, Palo Alto, Calif. Special awards were given to Detroit, Milwaukee, Brookline, Mass., New Haven, Conn., and Syracuse, N Y, all of which have twice won the award in their respective groups and were therefore excluded from the contest. In six geographic divisions the rural awards were as follows: northeastern, Cattaraugus and Westchester counties, New York; eastern, Kent County, Maryland; southeastern, Glynn County, Georgia; north central, Woodbury County, Iowa; south central, El Paso County, Texas; and western, San Joaquin health district, California. This contest is conducted in cooperation with the American Public Health Association.

Collapse of the Osteopaths' Attempt to Obtain Registration

At the tenth sitting of the committee of the house of lords on the bill for the registration of osteopaths, a volume was handed in which had been prepared in eight days by Dr W K Macdonald (a qualified physician who is also an osteopath) entitled "The Scientific Basis of Osteopathy." It embodied the seven "Bulletins of the A T Still Research Institute" which figured in the previous evidence, and contributions selected from the *Journal of the American Osteopathic Association*. It was a response to Lord Dawson's invitation to produce any scientific basis available. Sir Morton Smart, late medical officer in charge of the electrical department of the Hospital for Sick Children, Great Ormond Street, was the last witness called by the British Medical Association. He said that he had a large practice in manipulative surgery which was valuable in certain cases but should be based on a wide knowledge of anatomy and pathology and preceded by skilled diagnosis. In certain cases it could do great harm. He had studied the literature of osteopathy and found no scientific evidence for the theory. Both in America and in this country osteopaths while trying to adhere to the theory of Still, had ventured far from it and now used practically every method known to scientific medicine. They therefore realized that this theory cannot account for the causation of diseases. It was not in the public interest to give registration to a group of practitioners who based their practice on an unsound theory. If given the corollary was that the medicine of all civilized countries should be prohibited and it would be impossible to deny it to other cults such as chiropractors, nature curers and Christian scientists.

Prof G E Gask, director of the surgical unit at St Bartholomew's Hospital said that he had never been able to find anything which could be called an osteopathic lesion though since he had been called to the inquiry he had gone back to the wards and looked for it. Sir Norman Walker, president of the general medical council, presented a memorandum of evidence on behalf of that body. It could not find in the bill any definition of the scope of osteopathy or of the nature of that which was to be practiced. Its effect would be to exclude physicians from a field of practice which they possessed. On the other hand the medical acts contained nothing to prevent a physician from adopting any theory of medicine or surgery including osteopathy. Sir Arthur Robinson, secretary to the ministry of health presented a memorandum on behalf of the minister who held that there should be included in the statute a definition of osteopathy distinguishing it without possibility of mistake from other forms of practice. Unless this could be done, proper administration of the register would be impossible. It appeared to him that a sufficiently strong case had not been made out for the bill and that the proper action was to set on foot a scientific inquiry into the principles and practice of osteopathy. Mr S P Vivian, registrar general presented a memorandum on the importance of certificates of death. Unless the new class of practitioners were as fully equipped as the present class of registered physicians their admission would prejudice the important public interests served by certificates of death both to public safety and to medical statistics. He would regard any osteopathic evidence as to the cause of death as lay evidence. Mr R C Elmslie, surgeon in charge of the orthopedic department of St Bartholomew's Hospital and a member of the council of the Royal College of Surgeons gave evidence

on behalf of that body. He said that the education of the majority of those whose names would be placed on the register was not of a character which entitled them to be officially recognized and it would be impossible within any reasonable time to establish a system of education of osteopaths in any way comparable to that of the medical student. Risks were attached to manipulative treatment carried out by osteopaths who had not had an adequate training in diagnosis, and the theory of osteopathy was based on the presence of spinal lesions that had not been proved to exist.

The mass of expert evidence against the bill proved too much for the osteopaths. Their lawyer said that the medical profession had raised the issue that before a register was granted the osteopaths must produce scientific justification of their theory. He could not resist that issue and the committee was asked to make a finding on a matter that was beyond it. Moreover Dr Macdonald had said that he was not satisfied with the standard of the British School of Osteopathy. His clients therefore felt that they could not ask for that particular bill. But it should not be thought that they had lost any faith in their theories and they welcomed inquiry. A voluntary register of osteopaths would immediately be formed and as soon as possible a school qualified to give proper training would be constituted. The lawyer representing the Royal Colleges of Surgeons said that he was prepared to bring forward evidence severely commenting on the A T Still bulletins and other documents put in by the osteopaths. The committee decided to hear two further witnesses. Dr H K Graham, university teacher of radiology, said that the roentgenograms which had been put in to demonstrate osteopathic lesions were merely examples of adolescent curvature of the spine. He had submitted the statement made by Dr Macdonald that local edema and fibrosis could be shown in roentgenograms to experimental test and found it to be wrong. Sir Henry Dale, FRS, director of the National Institute of Medical Research said that the bulletins of the A T Still Institute submitted were of no scientific value. They were not attempts to discover the meaning of the suggested relation between particular spinal lesions and particular physiologic facts which might be valuable but were attempts to provide evidence for a theory already accepted. He did not think that the evidence tendered in "The Scientific Basis of Osteopathy" would justify the expenditure of public money on an investigation.

Thus after twelve sittings of the select committee of the house of lords, held over a period of nearly six weeks this attempt of the osteopaths collapsed. Their success in getting so far with their bill was due to the credulity always shown by a section of the British public for the claims of irregular practitioners. As the majority for the second reading of the bill in the house of lords shows, this section includes persons high in the social scale who indeed seem to be the most amenable to quackery. The vaunted cures ascribed to osteopathy seem to them most convincing. Success with the public engendered in the osteopaths an overweening conceit manifested by this attempt to obtain a status similar to that of physicians claiming that their fantastic theory was the key to the treatment of all disease—a claim which however broke down on cross examination. But it was the absence of any scientific basis for their theory that proved fatal. This point was driven home by the evidence of eminent witnesses, many of whom were engaged in purely scientific work or were high officials and were therefore not in practice and so were not open to the taunt of self interest. Thus the temporary success of the osteopaths only ended in discredit.

Anesthetic Explosions

At the Section of Anesthetics of the Royal Society of Medicine an anesthetist Dr Ironside, described an explosion that took place in a hospital. The anesthetic trolley had been in

use for two and one-half hours, with oxygen passing over ether. While it was being wheeled out of the operating theater into the anesthetic room a violent explosion occurred. The ether container broke into small pieces, and two bottles of ether on the other side of the room exploded. The theater attendant was knocked down, a sister was blown over, the patient fell off the trolley, and the whole room was a sheet of flame. The fire department was called and soon extinguished the fire. The floors and corridors of the hospital were laid with rubber, those of the anesthetic room and operating theater with granolithic flooring. The air in these two rooms was changed every ten minutes by a special apparatus supplying filtered air. The sterilizers were steamless, and the whole atmosphere was very dry. Nurses had complained of sparks from the trolleys carrying food or patients. The trolleys were insulated by rubber wheels. The anesthetic table was also on rubber wheels. A government expert put forward the theory that the explosion was caused by the oxygen passing through a metal tube to the ether container or by a spark from the patient's trolley. He also suggested that by bad luck the anesthetist had attained in the container the highest explosive mixture of ether and oxygen, 75 per cent of oxygen and 5 of ether. An important factor was a static charge of electricity when inflammable volatile substances were present. A discharge occurred when there was not sufficient moisture in the air to bring about earthing. Explosions appeared to be due to dust particles or droplets of liquid in the path of the electric current, which allowed discharge to take place. A source of discharge might be the rubbing of the covering of the gas bag on the rubber of the bag itself. To prevent such accidents the humidity of the air of the operating room should be increased and proper earthing should be secured to reduce the static risk. If the relative humidity of the room at 70 °F was 55 there was no guaranty against a static discharge.

Prof G. I. Finch dealt with ignition of explosive mixtures by discharge of static electricity, or by low tension arc discharges, such as could arise from rupture of an illuminating circuit. Explosion limits varied greatly according to the combustible and the supporting medium, whether air, oxygen or nitrous oxide. In the case of methane and air the explosive limits were between 5 and 14 per cent, of methane and oxygen, from 5 to 60 per cent. Little was known of the limits for nitrous oxide, but this gas was a more generous supporter of combustion than oxygen. Though under normal conditions ether-air mixtures were explosive only in the range of 15 to 75 per cent, mixtures of ether in air could propagate a cool flame, which traveled slowly and would not be detected except in a darkened room but was quite capable of producing an explosion. Although the nitrous oxide mixture for anesthesia was outside the explosion limit, it was impossible in practice to avoid subsequent dilution with air, which rendered the mixture explosive. Static discharges could be prevented by ensuring that all bodies which could come in contact with each other should be of equal potential. In an operating theater this called for efficient earthing of people, objects and controls.

The Prevention of Automobile Accidents

The latest measure for the prevention of automobile accidents is a speed limit of 30 miles an hour in built-up areas. At one time there was a general speed limit, but this was abolished and speed was punishable only when it could be shown to constitute dangerous driving. Red circular signs with the figure 30 marked on them have been set up on all the roads showing motorists when they enter the area in which their speed is limited. The exits from these areas are indicated by a circular sign showing a black bar drawn across a white background.

The Causes of Mortality in France—Syphilis, Tuberculosis, Alcoholism

An active discussion on the causes of mortality in France has been taking place at recent meetings of the Academy of Medicine. Roubakaine, a former expert in the section on hygiene, tried to show that the depopulation of France as claimed by some is a deception. Richet attacked the accuracy of the statistics quoted by Roubakaine as to the increase of deaths over births, and Rist, a well known authority, disputed the statements of Roubakaine as to the tuberculosis figures. Roubakaine maintained that the decrease in the number of births in France is a myth. In 1933 the birth rate in the principal countries of Europe was, per thousand inhabitants: Sweden 137, England 144, Germany 147, Belgium 165, Switzerland 165 and France 164.

In proportion to the number of inhabitants, the excess of births over deaths is lowest in Germany and next lowest in France.

With a population almost equal to that of Great Britain and Italy, the number of deaths in France greatly exceeds that of these other two countries, hence the apparent decrease in population.

The mortality during 1933 in France, 158 per thousand inhabitants, is relatively high as compared to that of Germany 112, Great Britain 123, Italy 140, Belgium 131, Switzerland 114, Holland 86, and Sweden 112. The only European countries having a higher mortality than France are Spain, Portugal and Rumania. These figures show that the cause of the relatively slight increase of population in France is not due to the decreased number of births but rather to the relatively high number of deaths as compared to other European countries. The number of births depends more on social and economic conditions, according to Roubakaine, than on any amount of governmental encouragement. Medical and sanitary organization alone cannot act in decreasing mortality, because this depends almost exclusively on the social and economic conditions of the masses, which dominate human biology. When one analyzes the causes of death in France, the most frequent cause is cardiovascular disease, which necessarily directs attention toward the incidence of syphilis. This disease affects from 8 to 10 per cent of the population in France. The syphilologist Fournier estimated it as high as 30 per cent. This calls for such measures as suppression of prostitution and its ulterior causes, such as unemployment, misery and white slavery. The number of deaths from tuberculosis is higher in France (1,516 per million inhabitants) than in any country of Europe except Finland. The infantile mortality, however, is small as compared to other countries. In France, as elsewhere, the percentage of deaths of illegitimate children is twice that of the legitimate. In 1933 there were 487,000 distilleries and saloons in France. Instead of directing attention to the necessity of more births, it would be far better to concentrate on combating the mortality from syphilis, tuberculosis and alcoholism, which are the real causes of the apparent denatality in France.

Richet challenged the accuracy of Roubakaine's figures but endorsed his statement that every effort must be made to decrease the number of deaths in France.

The mortality of new-born children has greatly decreased in nearly all countries during the past thirty years. The question of an increase in the number of births in any country is a purely voluntary one on the part of its inhabitants. In comparing the ratio of births to deaths, for a given population of certain European countries and that of Japan, the latter shows a much higher percentage.

The natality has greatly decreased in most European countries in comparison with that of Japan. In the case of Great Britain and Germany, this decrease in ratio is particularly striking. These two countries are at present at about the same level as France.

In the case of France the decreased ratio between births and deaths, as Professor Richet pointed out, is more serious than appears at first sight. From 1921 to 1931 about 1,300,000 foreigners came to France. The majority of these were adults. Hence the natality, or ratio of deaths to births, is much higher than in the case of the French native population. During this period (1921-1931) there were 55,000 births and 35,000 deaths among these foreigners. This foreign immigration is responsible for the small percentage, 0.5 per thousand, which represents the excess of births over deaths in France. In Austria and Sweden the percentage is 3 per thousand, while in Japan it is 15 per thousand.

The number of births was less in all European countries except Portugal, Greece and Ireland, in 1933 than in 1932. Professor Richet did not agree with Dr. Roubakaine that the aid given to young married couples and to those with large families had not greatly aided a rise in the natality ratio in Germany. Richet is of the opinion that legislative and economic aid play a far more important part in increasing the number of births than Roubakaine believes. If France would give a prize of 10,000 francs for every birth, there would be two million every year instead of only 661,000 as in 1933. The total number of births has decreased by about 400,000 in all European countries. This, in Richet's opinion, is not due to the economic crisis. Statistics show that such a factor does not play any part in the question. He believes that the number of births depends on the psychologic state of a people. The wards in Paris that represent the more prosperous portion of the population show the smallest number of births. The same is true of the departments of France. Hence the economic crisis cannot be held responsible. There are twenty-eight million births annually in Asia compared to one million in Europe (not including Russia). Professor Richet was alarmed by these figures and believed that the white races of Europe would be supplanted by the yellow, black and red races. If, in France, no effort is made in the near future to raise the number of births, the natality ratio will fall far below the present low percentage.

At the April 16 meeting, Roubakaine replied to the criticisms of Richet as to the inaccuracy of his statistics. As to the high mortality in France being due to the relatively large number of elderly individuals this was equally true of other countries or would be so shortly.

In the group above the age of 65, the mortality in France is 926 per hundred thousand and in England 828. Tuberculosis is the most common cause of death of elderly individuals in France. The immigrant population that has flocked to France since the World War is no more prolific than the native population. Twenty years ago France was at the bottom of the list of European countries as regards natality, but in 1933 it had moved up to sixth place and will rank still higher in the near future, if the present relatively high rate of births continues. He agreed with Richet that the natality is three times less in well-to-do families than in poorer ones.

Rist had challenged the statement of Roubakaine that France had a larger number of cases of syphilis, tuberculosis and alcoholism than any other country. Roubakaine cited the fact that, between 1920 and 1931, more than a million persons with syphilis applied for a primary consultation in public dispensaries. As to tuberculosis only four countries had a higher death rate from this cause than France. Of these four countries Hungary, Japan, Finland and Czechoslovakia, the last named had brought its death rate from tuberculosis to a lower figure than that of France.

The morbidity of tuberculosis has been greatly decreasing as the result of the excellent prophylactic work in France. This will no doubt greatly lessen the death rate in the near future. As to the consumption of alcoholic beverages, figures were cited showing that this is higher per inhabitant in France than in Germany, Italy or England.

Increases in the Average Height and Weight of Children

In the past twenty years, an increase in the average height and weight of school children has been observed. In Leipzig the increases, as announced by Dr. Koch in the *Deutsche medizinische Wochenschrift* amount to 11.6 cm. and 11.1 Kg respectively. This improvement has been regarded as an expression of an unusually good general condition. This phenomenon has been observed in Europe, America and Australia. The extensive Leipzig material, which goes back to 1918, covers the records of from 18,000 to 20,000 school children. This study revealed that the whole period of growth in man has undergone a material change. Although the length and weight of children at birth have changed but slightly, the rapidity of growth has been increased, so that the children equal in height children from one and a half to two years older of the prewar period. In both sexes there has been a compensatory shortening of the period of growth amounting also to from one and a half to two years. The height, after completion of growth, has not undergone a corresponding change, nor has there been much increase in the average body weights. In keeping with the accelerated growth, maturity is advanced to a corresponding extent. This is revealed in various ways, for example, by the onset of the first menstruation, which occurs about two years earlier than before the war (in Leipzig, at about age 13). Thus, this whole change, as Koch points out, is characterized by an approximation to the early development occurring in the tropical zones, to which in Germany, and apparently in other temperate regions, a whole generation appears to be subject. A premature aging of the population may possibly result from this early maturity. It is also likely that a corresponding advancement of the menopause will occur. If marriages continue to be contracted at the same average age as heretofore, the child-bearing period will be shortened by two years, which will effect a reduction in the number of births. As Koch points out this deficit in the number of births may jeopardize the federal government's attempts (thus far rather successful) to combat the low birth rate. These manifestations are assumed to be due to the fact that, during the past twenty years, the human body has been incomparably more exposed to the sun than formerly. This view is termed "the heliogenic acceleration of human growth" for, according to the observations of biologists, sunlight is capable of accelerating the growth and the maturation of living organisms.

The Relative Fecundity of Women

In connection with the sterilization law for the prevention of offspring with hereditary defects, the question as to the probability of a woman of a certain age having children is significant. Dr. Münzer and Dr. Löer have done research on the subject. For the year 1931 they found that, of all women just entering on the child-bearing period, whether married or unmarried, only about two thirds (68 per cent) have prospects of giving birth to a child. For this estimate the average length of life of 15-year-old girls is taken. Up to age 18 the probability of giving birth to a child remains for women who have had no children about the same as for those who are just entering the child-

bearing period. Beginning with age 19, the chances of a woman giving birth to a child become, at first slowly and then more and more rapidly, less and less, and reach, at the age of 45, which is usually regarded by statisticians as the upper limit of the child-bearing period, practically zero, although even at age 45 0.2 per cent of the women still give birth to a child. Further details are given in the tabulation.

*The Percentage of Women Who Having Had No Children,
Will Give Birth to a Child*

Age	Percentage to Bear Children	Age	Percentage to Bear Children	Age	Percentage to Bear Children	Age	Percentage to Bear Children
15	68	23	61	31	25	39	4
16	68	24	58	32	21	40	2
17	68	25	54	33	17	41	1.8
18	68	26	50	34	14	42	1.1
19	67	27	45	35	11	43	0.7
20	66	28	40	36	9	44	0.4
21	65	29	35	37	7	45	0.2
22	63	30	30	38	6		

The average number of children that a woman entering the child-bearing period is likely to give birth to was according to the fertility figures of 1931 only 1.72. This figure also remains about the same up to age 18 and with increasing age drops more and more rapidly, reaching at the age of 45 the value of 0.01 (these figures refer to the women who have given birth to one or more children). According to these figures, it is doubtful whether an increase in the fecundity of the older women can be brought about by the promotion policies of the government. Whether the fecundity of the younger women can be raised by such methods remains to be seen. These figures for 1931 give only the actual birth frequency—that is figures that are influenced by the willingness to bear children. The biologic birth possibilities, to judge from the results of the statistics on miscarriages, would doubtless be much higher—even for the women of the older age groups although after age 45 the number of children born would be exceedingly small.

The Hufeland Society

The Hufelandische Gesellschaft, which is one of the most honored medical societies of Germany celebrated recently its one hundred and twenty fifth anniversary. The society was founded in 1810 by Dr. Hufeland, Berlin's best known physician of that day, who made a place for himself in the history of medicine by his work 'Makrobiotik'. In that day a select group of representatives of various branches of medicine met once a week to discuss scientific questions. The Hufelandische Gesellschaft played a leading part for many decades—beyond the confines of Berlin in other regions of Germany. After the founding of the Berliner Medizinische Gesellschaft by Virchow and Graefe, in the second half of the previous century, the Hufelandische Gesellschaft concerned itself mainly with practical demonstrations. In this chosen field the Hufelandische Gesellschaft is still highly esteemed by practitioners because of the quality of the demonstrations. This society supports also a foundation for the rendering of aid to physicians and to the widows and orphans of physicians.

Influenza in Children

Finkelstein groups under influenza in children all the disorders of the respiratory passages that appear as an acute infectious catarrh. According to Dr. Nassau of Berlin 17 per cent of these disorders in childhood occur from May to August. The public continues to speak of colds, and some physicians consider chilling a causal factor in influenza but Nassau affirms that he can nearly always trace the disorder to an infection. Although the season influences the outbreak of the disease the severity and form of influenza are determined by

the age of the patient. Children under 6 months of age seldom suffer from an attack of influenza. Up to the fifth or sixth year, influenza takes a febrile course, with varying degrees of severity. Around the eighth to the tenth year, it takes the form of a troublesome catarrh, with little or no fever, and its harmlessness leads to the wrong impression that the number of attacks are decreasing. The children who suffer repeated attacks appear to belong to a special constitutional group. They are for the most part large boned and obese. The lymphatic tissues appear swollen and spongy, although there may be no actual enlargements. The skin is usually moist. A study of the family history reveals frequent cases of arthritis, a tendency to formation of kidney stones, rheumatism, and an early appearance of arteriosclerosis. Many children who are subject to frequent attacks presented an exudative diathesis as infants. Tonsillotomy has no influence on the predisposition.

ITALY

(From Our Regular Correspondent)

Feb. 28, 1935

The Academy of Medicine of Turin

The Academy of Medicine of Turin met recently under the chairmanship of Professor Tirelli. Battistini Cionini and Herlitzka discussed the influence of adrenal cortex extract on the metabolism of carbohydrates. They studied in normal persons the capillary and venous glycemia, and the venous lacticacidemia, following the injection of the cortical extract into the veins and the muscles, not only fasting but also after the administration of dextrose. After the injections while fasting, there usually resulted a diminution of the venous glycemia and an increase of the capillary glycemia. With dextrose there was a slight increase of the capillary and the venous glycemia. The extract always exerted a frank action on the lactic acid, which was always diminished. It was evident that even small doses of cortical extract act on the metabolism of carbohydrates in normal persons.

Marengo and Massimello reported their research on the skin tests for the diagnosis of icterus. Among various tests to detect light forms of hyperbilirubinemia and to distinguish the various types of icterus, the Klein test and the morphone test become positive when bilirubin blood values of from 0.6 to 0.7 mg. per hundred cubic centimeters are reached. The speakers usually found that the results of the two tests agree closely with a little less intensity for the morphone test. The Brugsch test is less sensitive. The tests mentioned aid in the diagnosis particularly of latent icterus, but they cannot replace the qualitative and quantitative determination of bilirubinemia.

Domici and Oliva reported observations on the effect that the protracted administration of vitamin A causes a marked increase of diuresis, which in patients affected with cirrhosis of the liver may reach values twice the normal quantity. The speakers consider it likely that the action of the vitamin on diuresis may be explained by the functioning of the liver.

Consultation Center for Pedagogic Medicine

At the observation center for wayward and abandoned children there has been created in Rome a consultation center, the purpose of which is to apply promptly to these young persons the treatment necessary for their physical and mental reeducation. The management of the consultation center has been entrusted to Professor Di Tullio, occupant of a chair in criminal anthropology at the University of Rome.

Bürger's Disease

Rolando of Genoa presented before the Società Piemontese di chirurgia the results of studies on the pathogenesis of Bürger's disease. To the results heretofore observed in the treat-

ment by means of removal of the adrenal capsule the author added his observations in two cases occurring in men aged 22 and 29 respectively, both subjected without avail to the removal of the left adrenal capsule, and, in a second operation to amputation of the hip and of the distal portion of the metatarsus. According to the speaker, persons affected with Bùrger's disease present a hypoplasia general or partial of the arterial system. Hence their tissues are insufficiently irrigated. Over a long period of time there may be adjustments but owing to added causes such as traumas, intoxications and tobaccoism, thromboses and small peripheral infarcts develop, the work of the heart increases and the organ hypertrophies. In the small arteries there is concentric hypertrophy of the tunica media, the epithelium becomes necrotic, and parietal thrombi develop, which later become total and occlude the vessel. The speaker emphasized the uselessness of the treatment heretofore in vogue, both medical and surgical.

Prof Ernesto Pestalozza

Prof Ernesto Pestalozza, senator, director of the Obstetrico-gynecologic Clinic of the University of Rome, died recently. He was of the school of Pavía. At the age of 30 he became director of a clinic. His scientific researches were prolific. His chief work was a series of studies on sarcoma deciduocellulare, which culminated with his research on chorioma. His operative methods in uterovaginal prolapse and in uterine retroversion have been accepted in the ordinary practice of the Italian and foreign gynecologic schools. He was an ardent journalist and was the director of the review *La ginecologia* which he founded at Florence.

Blood Changes in Radiologists

Addressing recently the Societe belge de radiologie, Dr Maisin considered the morphologic changes in the blood of radiologists. The circulating blood is not easily affected by radiations. The circulating blood in the ears of the rabbit may be irradiated for several hours without evidence of changes in the blood. On the other hand, the hematopoietic organs are very sensitive to radiations. One observes most frequently irritation of the red marrow. A permanent inversion of the white cells is observed at the same time. The relative number of the mononuclears is increased at the expense of the polymorphonuclears. If the irradiations are continued they eventually effect a persistent mild anemia with inversion of the blood picture in favor of the mononuclears; then the anemia becomes more marked under the effects of the rays and finally takes on an aplastic form, the aplasia affecting both the red cells and the white cells. As a rule, death intervenes with a purpuric syndrome and a noticeable diminution of the blood platelets.

The question arises as to where in this blood picture leukemia belongs. Leukemia must be regarded as a reactional condition due to an irritative state, whether of the lymphoid type, the myeloid type or the Blumenthal type in which an augmentation of the red cells and of the white cells is observed.

Two Belgian radiologists have died from leukemia. Nevertheless the leukemias are relatively more rare than the aplastic anemias. Recent statistics show that 25 per cent of the radiologists are affected with lymphoid leukemia. In 1913 Aubertin called attention to the inversion of the blood picture due to mononucleosis. Maisin taking account of only frank cases, noted in twenty-eight radiologists anemia 12 cases leukemia 5 cases mononucleosis 8 cases polynucleosis 4 cases polyglobulia 6 cases marked 12 cases relative. The anemia is usually mild; the most marked case presented 1 800 000

erythrocytes. The author observed anemia in very young radiologists and in elderly radiologists who had been exposed to rays over a long period. Leukopenia is the most grave sign. It may disappear with suitable rest and proper precautions. Mononucleosis is of less importance. It may develop sometimes after only a few weeks of professional practice and it has a tendency to be permanent. A suspension of practice for two months does not reestablish the normal blood picture. It persists sometimes after two or three years. It does not develop in all persons its appearance being due to an individual susceptibility. It may disappear during infections and reappear later in a graver form.

Polynucleosis is rare. It is not pathognomonic if there are elsewhere disorders capable of provoking it. It is found nearly always if there is any polyglobulia. It is an expression of irritation of the bone marrow.

Polyglobulia is found in young radiologists who are normally exposed and in elderly radiologists who have been slightly exposed over a long period of time. The highest figure was 6 300 000 erythrocytes. Young types are lacking. If the person affected takes a rest the figure will frequently drop to five or four million and will sometimes go below normal.

The reticulocytes—filamentous red cells—amount to about 1 per cent in a normal person but may rise to 20 per cent. They are an expression of an irritation of the bone marrow.

Is absolute protection possible? Yes, so far as diagnosis and therapy are concerned, but not for curietherapy. Four assistants in the radiotherapeutic department of the author have an absolutely normal blood owing to the use of adequate leaden screens. For the radiologist it is therapy that presents the gravest danger owing to the use of inadequate protecting screens and observation windows with insufficient protecting glass. These should be equipped not only with one thickness of leaden glass but also with sliding leaden shutters. One should be suspicious of joints of doors and should demand everywhere an adequate protection of lead.

BUDAPEST

(From Our Regular Correspondent)

April 12, 1935

International Dermatologic Congress at Budapest September 13-21

The ninth International Congress on Dermatology will deal with the pathology and therapy of skin diseases. Any qualified doctor can be a member of the congress provided he gives notice to his national secretary or to the organizing committee in Budapest, VIII Maria ucca 41, and at the same time submits the fee, which for ordinary members is 60 pengos (about \$15) and for invited nondermatologist members 30 pengos (\$7.50). The member fee entitles to the publications issued by the congress. The central bureau of the Congress is at the Budapest Dermatologic Clinic, VIII Maria ucca 41. The telegraphic address is Dermaklin, Budapest, the telephone number is 311-96. The congress will be in session from September 10 to 21 at Budapest V Vigado (a concert hall, telephone number 812-12). The official languages of the congress will be English, French, Italian and German. The following national secretaries have been appointed: United States, Howard Fox, 140 East Fifth-Fourth Street, New York; Argentina, Jose J. Puente, calle Santa Fe 995, Buenos Aires; Brazil, E. Rabello, 15 rua Alcindo Guanabara Rio de Janeiro; Mexico, Jesus Gonzales Uruena, Avenida Oaxaca 80, Mexico City; Uruguay, Jose Brito y Foresti, 1424 Rua Rio Branco, Montevideo.

Independently of the congress but at the same place September 14, the Union internationale contre le peril venerien will meet. No papers are admitted which have appeared either in whole or in abstract in any of the four official languages, prior to September 1.

THE FUNCTION OF THE COMMITTEES

The permanent committee of the international Dermatologic Association will determine the possibilities of bringing to life the International Dermatologic Association.

A second committee will endeavor to secure uniformity in the naming of skin diseases. Hereafter diseases should be named according to rational principles. The committee will announce that the terms psoriasis, lichen and pemphigus shall be applied only to the corresponding diseases. Such denominations as psoriasis palmaris syphilitica, herpes tonsurans and pemphigus syphiliticus should be discarded. The question of too long symptomatologic denominations, as erythema exudativum multiforme and erythema vesiculosum recidivens neurogenes will be decided by this committee.

A third committee, under the presidency of Howard Fox, will try to group skin diseases on the basis of modern pathogenic research. It will delimit the boundaries of dermatology from those of general diseases (syphilis, tuberculosis) and venereal diseases.

A fourth committee will deal with the principles of the most practical method of teaching medical students, postgraduate studies for practitioners, and the training of specialists. As teaching should be mainly visual, a lecture hall will be recommended that has a northern light and is equipped with modern apparatus for the demonstration of films, histologic preparations, experimental animals and, above all, patients. It is desirable that the dermatologic literature should be organized and made cheaper through international agreements.

A fifth committee will deal with the ways and means for interchanging histologic preparations between dermatologic institutes and supplying a great number of preparations of rare cases, and the establishing of a center for the interchange of photographs, moulages, histologic preparations, epilated hairs, parasites, cultures, antigens, vaccines and reprints. All exchanges are to be free of charge, excepting, of course, the costs of freight and postage.

A sixth committee will consider the present crisis in dermatologic practice, the question of clinics, social insurance, industrial cosmeticians, masseurs, quacks, the proportionate distribution of specialists to the population, the access of private practitioners to special hospitals, dermatology and the prevention of diseases, the compulsory notification of single diseases and the dermatologic enlightenment of the people, the responsibility of the dermatologist in practice, professional secrecy, and infections and injury threatening dermatologists, dermatology and eugenics, and the problem of sterilization.

All these committees will meet prior to the congress, so that on the last day of this congress the plenary meeting can vote on the proposals made by the committees.

Besides the six committees, four conferences will deal with dermatologic questions, chiefly from social points of view. 1 Skin tuberculosis. 2 The defense against venereal diseases. 3 The social aspects of skin diseases caused by industrial occupations. 4 A comparative dermatovenereologic conference. Some of the addresses will be made by Aynayd, on la stomatite pustuleuse des ovins, Balogh, on skin lesions in human glanders, Van Hedsborg, on poultry tuberculosis in men and in animals, Mócsy, on diseases caused by fly larvae, Siegfried, on lesions on the skin of milkers, Weidman of Philadelphia, on dermatoses of monkeys.

PROGRAM OF THE SPECIAL BRANCHES

1 The recently recognized functions of the skin. 2 Reciprocity, correlation and antagonism between the skin and the internal organs. 3 The role of allergy in dermatology and syphilology. Coca of New York and Hopkins of New York will read papers, Dr Coca speaking on the classification of allergic diseases of the skin, with diagnosis and treatment. 4

The disturbances of metabolism in dermatology, including avitaminoses and endocrinodermatoses. Whitfield of London will read a paper on dermatoses and disturbances of nutrition (excessive eating and drinking). Frasier of Peking will read a paper on the role of metabolism in dermatology. 5 The importance of external influences on the forms and frequency of skin diseases. The chief speaker will be Graham of London. 6 The importance of filtrable viruses in the etiology of skin diseases. Bayarri of Madrid, Levaditi of Paris and Eagles of London will read papers. 7 The latest achievements in the field of tuberculous skin diseases. 8 The immunobiologic, non-specific and medicinal treatment of syphilis. 9 The criteria of the cure of syphilis.

SPECIAL LECTURES

- 1 Sabouraud of Paris. The evolution of dermatomycology.
- 2 Memorial lectures by Hoffmann of Bonn and Rille of Leipzig.
- 3 Riecke of Göttingen. The present position of dermatology in the medical sciences.
- 4 Mariani of Bari, Italy, and Siemens of Leiden, Holland. Genodermatoses.
- 5 Morrow of San Francisco, Rogers of Hampstead and Reuss of Shanghai. Recent achievements in the treatment of leprosy.

INDIVIDUAL PAPERS IN SEPARATE HALLS

In addition to papers on the main themes, Andrews of New York will discuss pustular bacterids, Bodon of Budapest, un nouveau traitement de la douleur de l'aortite syphilitique, Castellani of London, less known tropical skin diseases, Kenyeres of Budapest, the forensic aspects of treatment with thallium, Pearce of New York, animal syphilis. Other papers will be read by Harrison of London, O'Leary of Rochester, Minn., and Thomkinson of Glasgow, among others.

OFFICIAL PUBLICATIONS OF THE CONGRESS

In addition to the main report on the transactions of the congress there will be reports on the work of the committees and conferences and a memorial volume on the evolution of modern dermatology in the last fifty years compiled from the works of Bechet, Howard Fox, Howard Fox Jr., Pollitzer of New York, Pusey of Chicago, Castellani, Graham Little of London, Darier, Sabouraud, Dubreuilh of Bordeaux, Jadassohn of Zurich, Matsumoto of Kyoto, Marcus of Stockholm, Hoffmann of Bonn, Rille of Leipzig, Peyri of Barcelona, Truffi of Padua, Riehl of Vienna, and Torók of Budapest. There will also be a catalogue of the exhibitions.

EXHIBITS

There will be three exhibitions. 1 Dermatologic relics, medals, plaquettes, souvenirs, pictures, manuscripts, documents, books, apparatus and instruments. 2 Modern histologic preparations, photographs, moulages, charts, reports of analyses, statistical graphs, collections of parasites and cultures, vaccines and toxins. A mycologic exhibit will be demonstrated by Arzt of Vienna, Rivalier of Paris, Castellani of London and Benedek of Leipzig. 3 Industrial exhibits: optical, electrical, radiologic, thermal, mechanical and chemical instruments and apparatus, laboratory and operating equipment, drugs and dressings, administrative and hospital equipment, nursing, cosmetics, dietetic and curative articles of food, also periodicals and books. An international jury will award prizes and medals to the exhibitors.

The IBUS (Hungarian Enterprise for Encouraging Foreigners to Come to Hungary) will ensure members first class hotels and boarding houses, according to three different categories (as to price).

Special committees will arrange excursions, entertainments, concerts and recitals for ladies who accompany their husbands.

Marriages

HARRY JOHNSON SCHMIDT, Convent, La, to Miss Margaret Mary Heath of New Orleans at Ocean Springs, Miss, May 25
LAWRENCE P COGSWELL, New York, to Miss Marjorie Smith Garde of New Haven, Conn, at Hartford, Conn, May 18
JOSEPH LEROY STEVENS to Miss Ruth Wager Turner both of Dayton, Ohio, at Richmond, Ind, Dec 6 1934
ROBERT WILSON JR, Charleston, S C, to Miss Gabrielle Palmer McColl of Bennettsville, April 27
THOMAS ARCHER GIBSON, Winchester, Va, to Miss Helen Hawke of Clifton Heights, Pa, May 4
WILLIAM MERVEN SEABOLD, Boston, to Miss Esther Jeanette Solomon of Newton, Mass, May 4
EDWARD M HOLMES JR, Richmond, Va to Miss Sarah Daily Walsh of Norfolk, April 27
DAVID MANNING WOLFE to Miss Georgia Louise Neal, both of Augusta, Ga., April 23
CLINTON R COULTER, Parkers Landing, Pa to Miss Virginia Evelyn Glazier, May 2
ROSS PARKER COV, Rome, Ga to Mrs Julia B Holland of Atlanta, March 5

Deaths

Elizabeth Bnrr Thelberg, Poughkeepsie, N Y, Woman's Medical College of the New York Infirmary for Women and Children, New York, 1884, member of the Medical Society of the State of New York for many years professor of hygiene and physiology at Vassar College, chairman of the Medical Women's National Association, past president of the Medical of Women, member of the executive board and at one time director of American Women's Hospitals and was decorated by France and Serbia for work in this organization, which maintains hospitals and clinics for the destitute in various foreign countries, aged 74 died, April 22, of diabetes mellitus and coronary thrombosis
Arthur Cushing Pearce, Boston, Harvard University Medical School, Boston, 1903, member of the Massachusetts Medical Society at one time assistant instructor in pathology and bacteriology and instructor in genito urinary diseases Tufts College Medical School aged 59, for many years on the staffs of the Boston Lying-in Hospital and of the Boston City Hospital where he died, March 16 of coronary thrombosis
William Royster Thompson of Lexington Ky University of Louisville (Ky) Medical Department 1892 formerly health officer of Montgomery County and member of the board of health for many years assistant physician and psychiatrist of the Eastern State Hospital aged 64 on the staffs of the Good Samaritan Hospital and St. Joseph's Hospital, where he died, April 29, of pneumonia
Julius Ola Cobb of Senior Surgeon, U S Public Health Service, Los Angeles Medical College of the State of South Carolina Charleston, 1883 veteran of the Spanish-American War, member of the American Clinical and Climatological Association fellow of the American College of Surgeons, aged 72 died, March 26
Walter Andrew Crowe, Smyrna, Ga Bellevue Hospital Medical College, New York, 1881, member of the Medical Association of Georgia fellow of the American College of Surgeons at various times on the staffs of the Grady and Wesley Memorial hospitals and St. Joseph's Infirmary, Atlanta, aged 78, died, April 4, in the Georgia Baptist Hospital, Atlanta
George William King Secaucus, N J, University of Michigan Department of Medicine and Surgery Ann Arbor, 1879 member of the Medical Society of New Jersey, and the American Psychiatric Association for many years superintendent of the Hudson County Hospital for Mental Diseases aged 78 died suddenly, April 15, of cerebral hemorrhage
Clifford Robert Weiss of Dayton Ohio Ohio State University College of Medicine, Columbus, 1921, fellow of the American College of Physicians member of the Radiological Society of North America aged 39 on the staffs of St. Elizabeth's Hospital and the Good Samaritan Hospital, where he died April 2 of pulmonary tuberculosis
Matthew Carroll Baines, Canandaigua, N Y, Jefferson Medical College of Philadelphia 1903 member of the American Psychiatric Association and the Association for Research in

DEATHS

1923

Nervous and Mental Diseases served during the World War manager of the Veterans Administration Facility, aged 60, died, April 23, at Rochester, Minn
Joseph Augustus Mulholland, New York, Cornell University Medical College, New York, 1900, member of the Medical Society of the State of New York, fellow of the American College of Surgeons, served during the World War, on the staff of St Vincent's and New York Foundling hospitals, aged 56, died, April 4
John Lear Treacy, Helena Mont, Rush Medical College, Chicago, 1910, member of the Medical Association of the State of Montana, served during the World War, on the staffs of St. Peters and St John's hospitals member of the school board, aged 50 died, February 24, of cirrhosis of the liver
Joseph Henschel of New York College of Physicians and Surgeons, Medical Department of Columbia College New York Hospital and St. Elizabeth's Hospital, aged 63, died suddenly, May 1 of coronary thrombosis, while delivering a lecture.
David Ellsworth Clopper, Kansas City, Kan., University Medical College of Kansas City, 1896, member of the Kansas Medical Society, formerly mayor of Argentine, member of the school board, aged 67, died, March 15, in the Providence Hospital, following an operation for appendicitis
Clyde Richard Nicholson, Statesville N C, North Carolina Medical College, Charlotte, 1912, member of the Medical Society of the State of North Carolina, aged 45 on the courtesy staff of the H F Long Hospital, where he died, April 13, of hypernephroma of the right kidney
Albert August Axley of Washburn, Wis, Rush Medical College, Chicago, 1912, served during the World War, formerly health officer, president of the board of education medical superintendent of the Washburn Hospital, aged 47, died, April 16, of cerebral hemorrhage
George Frederick Curley, Milford, Mass, Jefferson Medical College of Philadelphia, 1896 member of the Massachusetts Medical Society, fellow of the American College of Surgeons, on the staff of the Milford Hospital, aged 62, died, April 15, of heart disease.
Joseph Stephen Healy, New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1890 member of the Medical Society of the State of New York, aged 77, died, March 9, in the New York Eye and Ear Infirmary
Charles Daniel Chambers, Selmer Tenn Memphis Hospital Medical College, 1912, served during the World War, aged 46 died April 21 in the Veterans Administration Facility, Memphis, of peritonitis, following an operation for ruptured appendix
William A Carpenter, Cleveland, Miss, Mississippi Medical College, Meridian, 1909, member of the Mississippi State Medical Association, at one time health officer of Lauderdale County, aged 49, died, February 26, of lobar pneumonia
Harry J Bennett, Lincoln Park, Mich, Queen's University Faculty of Medicine, Kingston Ont Canada 1905 aged 56, died, April 26 in the Wyandotte (Mich) General Hospital, of injuries received when he was struck by an automobile
William Ernest Packwood, Riverton, Neb, Bennett College of Eclectic Medicine and Surgery, Chicago, 1906 member of the Nebraska State Medical Association, aged 58, died, March 5, of cerebral hemorrhage and arteriosclerosis
James Clyde Johnson of Richmond, Texas Tulane University of Louisiana Medical Department, New Orleans, 1884, president of the Fort Bend County Medical Society, aged 71, died, April 22 of coronary occlusion.
Edward Manning R Casey, Montreal, Que., Canada, McGill University Faculty of Medicine, Montreal, 1928, member of the Associated Anesthetists of the United States and Canada aged 34 died, March 29
Young Ernest Colville, Hilo, Hawaii, Chattanooga (Tenn) Medical College, 1903 member of the Hawaiian Territorial Medical Association, aged 57, died, January 30, of myocarditis, arteriosclerosis and hypertension
Frederick P B Bender of Detroit, University of Michigan Department of Medicine and Surgery Ann Arbor, 1902 served during the World War aged 60, died, April 8, in the Jefferson Clinic and Diagnostic Hospital
Hermann Christopher Hoefling of New York College of Physicians and Surgeons Medical Department of Columbia College New York 1885 aged 74, died, April 4, in the New York Hospital of carcinoma

Carroll Reid Copple, Keyesport, Ill., National University of Arts and Sciences Medical Department, St. Louis, 1914, served during the World War, aged 42, died, April 19, of pulmonary tuberculosis

William Ford Botts, Center, Mo., Kansas City Medical College, 1897, member of the Missouri State Medical Association, formerly mayor of Santa Fe, aged 62, died, February 1, of angina pectoris

Lewis Rousseau Scudder, Ranipet, Arcot, India, University of the City of New York Medical Department, 1888, for many years a medical missionary, aged 73, died, April 18, of heart disease

Wellman D. Conn, Bambridge, Ind., Louisville (Ky.) Medical College, 1893, member of the Indiana State Medical Association, aged 74, died, April 4, in the Putnam County Hospital, Greencastle

Ernest Le Roy Bennett, Bainbridge, N. Y., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1888, aged 69, died, March 13, of gastric carcinoma

Thomas Bailey Marquis, Hardin, Mont., University Medical College of Kansas City, Mo., 1898, served during the World War, aged 65, died suddenly, March 22, of acute dilatation of the heart

William Duncan McKim, Washington, D. C., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1878, aged 80, died, April 11, in Pasadena, Calif.

Francisco J. Rucavado, Chicago, Northwestern University Medical School, Chicago, 1893, aged 76, died May 6 in the Mercy Hospital, of prostatic hypertrophy and chronic nephritis

Judge Barclay Cruse, Beaumont, Texas, Vanderbilt University School of Medicine, Nashville, Tenn., 1893, member of the State Medical Association of Texas, aged 65, died, April 22

Allen Douglas Brown, Mineral Point, Wis., Rush Medical College, Chicago, 1883, formerly mayor, aged 76, died, April 12, in St. Joseph's Hospital, Dodgeville, of coronary embolus

Oscar Augustus Newman, Harrisburg, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1897, aged 60, died, February 23, of carcinoma of the left lung

Thomas W. Swalm, Pottsville, Pa., New York Homeopathic Medical College, 1878, for many years member and president of the board of education, aged 79, died, April 5

John Luther Campbell, Birmingham, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1880, aged 77, died, April 21, of coronary thrombosis

William Edgar Hare, Garnett, Kan., Eclectic Medical University, Kansas City, 1910, member of the Kansas Medical Society, aged 73, died, February 10, of angina pectoris

Walter Samuel Hargett, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1905, aged 55, died, March 9, at his home in Penn. Valley, Pa.

Charles Otto Lowry, Pasadena, Calif., Central College of Physicians and Surgeons, Indianapolis, 1896, aged 61, died, February 25, of chronic myocarditis and nephritis

Charles Fisher Mills, Pismo Beach, Calif., Harvard University Medical School, Boston, 1882, aged 74, died, March 31, of heart disease, hypertension and arteriosclerosis

James Edward Dempsey, New York, Harvard University Medical School, Boston, 1911, aged 51, on the resident staff of the Riverside Hospital, where he died, April 9

Frederick Eben Cummings, Concord, N. H., Dartmouth Medical School, Hanover, 1882, aged 76, died, April 4, of cerebral hemorrhage and diabetes mellitus

John Allison Coen, Cameron, W. Va., University of Pittsburgh School of Medicine, 1911, served during the World War, aged 48, died, April 9, of angina pectoris

William Sloane Orr, Denver, Denver Homeopathic College, 1905, served during the World War, aged 71, died, February 17, as the result of an automobile accident

William Brady Sharkey, Clinton, Ill., St. Louis University School of Medicine, 1924, aged 35, died April 13, in the Dr. John Warner Hospital, of pneumonia

Martin John Waldron Jr., Denver, Denver and Gross College of Medicine, 1904, aged 53, died, April 6, in St. Anthony's Hospital

Edwin W. Haradon, Old Hickory, Tenn., State University of Iowa College of Medicine, Iowa City, 1886, aged 72, died April 11, of cerebral hemorrhage

Charles Walter McColl, Wyandotte, Mich., Detroit College of Medicine, 1895, member of the Michigan State Medical Society, aged 69, died April 1

Archer Wilson Paulette, King City, Mo., Central Medical College of St. Joseph, Mo., 1896, aged 62, died April 1, in Salisbury, of coronary embolus

William M. Hilley, Sidney, Texas (registered by Texas State Board of Medical Examiners under the Act of 1907), aged 59, died, February 25

Samuel Shaw Crumbaugh, Toledo, Ohio, Medical College of Ohio, Cincinnati, 1872, aged 87, died, April 4, of arteriosclerosis and myocarditis

John Henry Watson, Chicago, McGill University Faculty of Medicine, Montreal, Que., Canada, 1895, aged 64, died, April 19, of myocarditis

Henry Stein, Altamont, Ill., Missouri Medical College, St. Louis, 1894, for many years president of the school board, aged 65, died, April 16

Wyatt Hutchins Alexander, Blakely, Ga., Atlanta Medical College, 1895, member of the Medical Association of Georgia, aged 60, died, April 17

Carl Eugene Schulte, St. Louis, College of Physicians and Surgeons, Keokuk, Iowa, 1896, aged 67, died, April 10, of cirrhosis of the liver

Robert William Haynes, Long Beach, Calif., University of Pennsylvania Department of Medicine, Philadelphia, 1881, aged 74, died, March 16

Henry Merrill Barrett, Mount Elgin, Ont., Canada, Western University Faculty of Medicine, London, 1912, aged 45, died, March 18

Frank Maxon Taylor, Portland, Ore., University of Oregon Medical School, Portland, 1901, aged 61, died, April 1, in the Emanuel Hospital

Frank D. Glenn, Blairsville, Pa., Western Pennsylvania Medical College, Pittsburgh, 1904, aged 55, died, March 9, of diabetes mellitus

John Alexander Heatly, Schenectady, N. Y., Albany Medical College, 1887, aged 72, died April 3, of gastric ulcer and hemorrhage

Samuel Newell Smith Jr., Providence, R. I., Cornell University Medical College, 1905, aged 53, died recently of lobar pneumonia

Richard P. C. O'Brien, Minneapolis, Chicago Medical College, 1885, aged 72, died, April 4, of coronary thrombosis and myocarditis

Aaron James Hunter, Orangeville, Ont., Canada, Victoria University Medical Department, Coburg, 1887, died January 31, of septicemia

Simon Miller, Mondovi, Wis., University of Pennsylvania Department of Medicine, Philadelphia, 1870, aged 86, died April 23

William McEnery Brown, Neustadt, Ont., Canada, Trinity Medical College, Toronto, 1884, L.R.C.P., London, 1884, died April 14

Edwin Ferdinand Corbell, Sunbury, N. C., University of Maryland School of Medicine, Baltimore, 1886, aged 73, died, April 11

Leo Francis Bonner, Paulsboro, N. J., Hahnemann Medical College and Hospital of Philadelphia, 1928, aged 30, died April 23

Harry H. English, Conesville, Iowa, Keokuk Medical College, College of Physicians and Surgeons, 1901, aged 72, died, April 2

Marshall L. Bacon, Concord, Mich., Detroit College of Medicine, 1890, aged 76, died, April 28, of cerebral hemorrhage

Louis Nazaire Turgeon, St. Prime, Que., Canada, Laval University Faculty of Medicine, Quebec, 1922, died, February 19

John S. Mortlock, Los Angeles, Hahnemann Medical College and Hospital, Chicago, 1878, aged 84, died, February 1

Joseph H. Hall, Norman Park, Ga., University of Georgia Medical Department, Augusta, 1889, aged 68, died, March 1

Carl George Rahal, Los Angeles, University of Oregon Medical School, Portland, 1908, aged 48, died, February 9

Dugald McKenzie, Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1886, aged 74, died, April 1

Abraham U. Chase, Tiff City, Mo., Marion Sims College of Medicine, St. Louis, 1892, aged 67, died April 4

Archie Griffin, Valdosta, Ga., Louisville (Ky.) Medical College, 1894, aged 65, died May 2, of pneumonia

Herman Burgin, Philadelphia, Jefferson Medical College of Philadelphia, 1879, aged 84, died, April 14

Henry Snyder, Brooklyn, Long Island College Hospital, Brooklyn, 1906, aged 53, died April 16

Correspondence

A SIMPLE AND EFFICIENT PATCH TEST

To the Editor—Because of the complicating dermatitis that occurs after the use of any adhesive agent, such as tape or the glue-like substance that has been used on the cotton felt rings, the following simple method has proved effective. It eliminates the use of rubber tissue or any agent that might produce a dermatitis through allergy.

A circular piece of sterile absorbent cotton about the size of a silver dollar (38 mm) and from 0.5 to 1 cm thick is used and the suspected agent is placed on this. If a powder is used, an amount covering an area about 1 cm square is placed in the center of the cotton; if a liquid is used a small piece of cotton 1 cm square may be soaked with the agent and placed in the center of the circular pad of cotton.

After the skin has been cleansed with ether, this cotton pad is placed with the agent against the skin on the site chosen, usually the upper part of the back. Flexible collodion is used to stick the test pad to the skin and this is well coated with the collodion. The patient is instructed to return for examination after twenty-four or forty-eight hours and a part of the patch may be loosened for examination and then resealed.

This simple method has proved adequate with insecticides, bakelite powder, soda solution and oil.

H. S. REYNOLDS, M.D., Hartford, Conn.

INFECTION OF NURSES WITH TUBERCULOSIS

To the Editor—The communication of Dr. H. J. Ustvedt in *THE JOURNAL*, March 9, page 851, touches several important problems. The nurses who enter the Ullevaal Hospital in Oslo with negative tuberculin reactions are all apparently infected with tubercle bacilli during a three year period of training. This experience, combined with the additional observation that in this interval 48 and 34.6 per cent of the nurses who entered the institution with positive and negative tuberculin reactions respectively developed clinical tuberculosis, illustrates the need for the routine observance of strict contagious technic by all who are attending tuberculous patients. Violations of basic principles of communicable disease control by the staffs of hospitals retard the progress of programs designed to eradicate tuberculosis. This situation, prevalent doubtless in hospitals throughout the world, merits immediate correction under the leadership of the medical profession, otherwise a penalty in the form of new cases of clinical tuberculosis of institutional origin continues to be paid for permitting infection to occur.

Dr. Ustvedt presents valuable data derived from studies now in progress in Oslo which he interprets as significant evidence that tuberculin sensitive individuals withstand exposure to infection more successfully than normal uncontaminated persons do.

Certain observations (to be published in the *American Journal of Diseases of Children*) made at Lymanhurst however fail to support this view. During the past thirteen years we have observed and traced 183 children who without exception experienced pulmonary infections in dosage sufficient to produce infiltrations demonstrable on chest films. On the basis of repeated examinations the lesions were recognized as tuberculosis of the first infection type in 131 instances, and as phthisis in the remaining fifty-two cases. One of the group of 131 children with primary tuberculosis died of tuberculous meningitis. In the remaining 130 cases of this series the infiltrations resolved in time without requiring the aid of therapeutic measures to leave several examples each of roentgeno-

graphically negative lungs, Ghon tubercles, calcified mediastinal glands or fibrotic scars. Not one of these pneumonic lesions producing first infections resulted in phthisis.

The experience of these 131 freshly infected children with primary tuberculosis was quite different from that observed for the remaining fifty-two patients who on admission had positive tuberculin reactions and no roentgenologic evidence of phthisis but developed tuberculous pulmonary infiltrations subsequent to their entry to the clinic. These fifty-two new lesions known in each instance to be the result of superinfections and not the immediate product of first infections manifested characteristics deemed typical of phthisis in tending to persist, to spread, to cavitate and to cause illness. In spite of special therapy, thirteen of these patients have died of tuberculosis and several additional cases now show far advanced disease. Not one of the fifty-two reinfection lesions has resolved in the manner exhibited by over 99 per cent of the 131 observed first infection infiltrations. Statistical analysis of these data, involving the computation of chi-square, reveals the existence of no chances per million for accidental sampling to explain the observation that infections capable in all instances of producing pulmonary infiltrations consistently result in a relatively benign type of tuberculosis but fail to cause phthisis when they are primary in nature, whereas lesions producing superinfections or reinfections consistently result in phthisis, a relatively serious condition. This observation is interpreted as significant evidence that a susceptibility to the reinfection or adult type of pulmonary tuberculosis resides solely in patients who have survived the immediate risks that attend an initial infection. By virtue of this dangerous susceptibility created by a first infection, a direct causal relationship seems to exist between primary tuberculosis and phthisis. Apparently the latter develops solely following the antecedent presence of the former, which produced complex abnormal immunologic changes favoring this situation. A susceptibility to phthisis is a serious double liability. Its materialization claims many lives and at the same time it permits the origin of the form of the disease which perpetuates a major health menace. The solution of this public health problem seems to depend mainly on preventing infections rather than on placing reliance on an alleged postinfection acquired immunity.

The use of different methods for classifying tuberculosis may explain a part of the failure of deductions based on independent but otherwise similar studies to be in agreement. Apparently greater attention is paid at Lymanhurst than at Oslo in differentiating the benign primary from the more serious reinfection forms of tuberculosis. This differentiation is made at Lymanhurst on the basis of several points, including knowledge of previous tuberculin reactions, serial x-ray plates and clinical observations. When differentiated on this basis, the death rate observed for the first infection type of pulmonary tuberculosis exhibiting parenchymal infiltrations was found to be 0.76 per cent (one of 131 cases) as compared with a rate of 25 per cent (thirteen of fifty-two cases) for the cases diagnosed as examples of phthisis. Statistical analysis of these observations, employing the computation of chi-square reveals the existence of no chances in a thousand for the difference between the high but as yet incomplete death rate for patients considered to have phthisis as compared with the low and probably final primary tuberculosis death rate for children with lesions diagnosed as the first infection type to be due to accident. These observations are interpreted as reliable evidence that the type of pulmonary tuberculosis present in one of our series of cases is a clinical entity distinct from that present in the other, that the separate identification of these two conditions has been carried out correctly at Lymanhurst, and lastly that normal children control lesion-producing first infections far more satisfactorily than tuberculin-sensitive individuals resist

lesion-producing reinfections. A superior ability to combat tuberculosis seems to be possessed therefore by the previously uncontaminated child.

Before the theory that a tuberculous infection produces a worthwhile immunity can be accepted without qualifications, indisputable evidence should be presented to show that the initial deposit of tubercle bacilli does not create a susceptibility to phthisis and that primary foci of disease are not parent eventually in many instances to clinical forms of the disease of endogenous origin such as tuberculosis of serous membranes, of bones and joints, of different viscera, or of phthisis.

These possible potentialities which often are months or years in materializing, combined with the more immediate serious catastrophes that complicate a certain percentage of first infections with virulent tubercle bacilli, must be balanced as liabilities versus the immunity alleged to arise from a primary infection, before an experience of this character can be definitely identified as conferring positive net benefits on the patient.

Considerable justification exists, I believe, for being reluctant to accept the excellent work in Oslo as final proof that net benefits consistently accrue to those who become contaminated with virulent organisms. The divergence of the opinions derived from independent studies directed toward solving perplexing and important questions is stimulating. Dr. Ustvedt's communication focuses attention on crucial problems that invite investigators to aid one another in a continued search for the truth.

C. A. STEWART, M.D., Minneapolis

PERFUME DERMATITIS

To the Editor—I read with a great deal of interest the article by Dr. Norman Tobias on "Emeraude Perfume Dermatitis." In an article on "Lipstick Dermatitis" to be published in the *Archives of Dermatology and Syphilology*, I describe work in which it was found that the factor was the perfume component and the specific substance of the perfume component (methyl heptene carbonate). This is a new synthetic derived from ricinoleic acid and is widely used by the perfumers for violet odor. I have found over 50 per cent of both men and women sensitive to this substance by the patch test.

In his conclusion, Dr. Tobias mentions three possible causative factors in perfume dermatitis, namely, concentration of the perfume, irritants due to aging, and sunlight. I do not know whether or not emeraude contains methyl heptene carbonate, but from my limited observations I believe that this substance is of prime importance in the development of a dermatitis in which perfume may be a factor. Perfumers have recognized methyl heptene carbonate as an eczematizing agent and are eliminating it.

HARRY LEONARD BAER, M.D., Pittsburgh

OSTEOPATHY AND LICENSURE

To the Editor—Every earnest physician should have a liberal supply of reprints of the article by Etherington on this subject (*THE JOURNAL*, April 27, p. 1549) for distribution to the public. It is quite superior to anything that has been published.

I still have in my files roentgenograms of a neck which one of the ilk succeeded in fracturing in the then faddish treatment of polishing up the upper end of the spine.

The woman lived several years. She was seen by Dr. Goldthwaite of Boston, and later at autopsy by Dr. J. D. Pilcher, under the direction of the late Dr. Carl Hamann, who was present the fracture was verified.

It may not have been a misfortune to the public that this same chap ultimately located in Chicago, whence shortly afterward he migrated to a place where they probably use some sort of heat, generated by brimstone, for fusing his breaks.

W. F. BROKAW, M.D., Cleveland

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

EFFECTS OF EXERCISE ON GASTRIC ULCER

To the Editor—What is the current opinion as to the effect of physical exercise either moderate or violent on a gastric or duodenal ulcer in its quiescent stage in an adult of middle age? Please omit name and address.

M.D. New York

ANSWER.—Recent study (Hellebrandt, F. A., and Dimmitt, L. L. *Am J Physiol* 107:355 [Feb.] 1934) has shown that, in general, violent exercise shortly before eating definitely inhibits gastric secretion and motility but that this first phase of inhibition of the digestive cycle is followed by a period of augmented activity. The hypersecretion and hypermotility already present in these patients would therefore be increased and for this reason violent exercise should be contraindicated in a patient of middle age with a gastric or duodenal ulcer in its quiescent stage.

Moderate exercise is as a rule advised by most gastro-enterologists as part of a system of hygienic living for the ulcer patient (Harris, Seale. *J Oklahoma M A* 26:287 [Aug.] 1933). Ulcer patients prior to dismissal are given an outline of a system for hygienic living, as follows: "Fifteen minutes exercise with the windows wide open before the morning bath. Follow the bath with massage (brisk rubbing with the open hand) of the entire body, until the skin is reddened. A walk of one or two miles in the open air and sunlight each day or, what is better, play golf two or three afternoons a week." In addition there is advised "eight hours for play," which includes morning exercise, bath, golf or outdoor exercises.

It is important to realize that the treatment of an ulcer patient must have as its objective the treatment of the entire patient. This includes to a large extent elimination of the nervous stresses and strains as well as local therapy directed at the ulcer. No ulcer patient should be subjected to a competitive golf match or to any other exercise that increases nervous tension. As far as possible these individuals should be taught serenity and relaxation both in their vocations and in their avocations.

ACUTE NEPHRITIS IN A CHILD

To the Editor—In May 1934 I saw a boy aged 11 who following a mild respiratory infection began to pass urine of a reddish color. There was also at the onset some puffiness of the eyelids and his mother stated that his face looked a little swollen. These symptoms were noted by the patient's mother for two weeks before I was called to see him. During this time he had attended school and was about as active as usual. At the time of my first visit the patient showed moderate edema of the eyelids and face. He was pale, the hemoglobin was 55 per cent. The temperature was 100 F, the pulse was 90 and respirations numbered 20. The heart, lungs and abdomen were normal. There was no edema of the extremities. The urine was smoky, was red and contained 3+ albumin. There were numerous red blood cells and hyaline and granular casts. The blood pressure was 140 systolic, 100 diastolic. He was put on a diet poor in salt, high in carbohydrates and with enough protein to care for his needs. Fluids were moderately restricted. He was ordered to remain in bed. On this regimen he gradually improved. In two months the albumin, blood and casts were no longer found. There was no edema. The blood pressure, however, remained high but with variations. The systolic pressure ranged from 130 to 170 and the diastolic from 90 to 115. He was kept in bed for a month after the urine cleared up. He was then allowed up part of the time. This seemed to make no difference in the urine and the blood pressure averaged the same as when he was in bed. He has definitely impaired renal function for the maximum specific gravity attainable on a concentration test is 1.014. His non-protein nitrogen is 60 mg. per hundred cubic centimeters of blood although the value for creatinine is normal being 1.73. Here then is a boy with chronic glomerulonephritis, hypertension, impaired renal function and nitrogen retention. I need advice on the following questions: 1. At this stage should bed rest be enforced? 2. What is the usual prognosis in a case of this kind? Any suggestions as to diet or management of this case will be greatly appreciated. Please omit name.

M.D. Wisconsin

ANSWER.—1. Five or six months has passed since this child had an attack of acute nephritis, and the condition may now be regarded as subacute or chronic. Since there is no evidence of an active infection, the boy may be out of bed, and he may be allowed activity and exercise, though not up to the point of fatigue.

2. The prognosis in such a case will vary with the extent of actual anatomic damage to the kidney tissues. Many of these

children recover entirely if no additional acute attacks of nephritis occur. It should always be remembered that the recuperative powers of a young person are comparatively greater than those of an adult.

As to the diet and management of such a case, it is being generally accepted that a more liberal diet than was formerly allowed is advisable. Enough protein should be allowed to keep the patient in a positive balance, and this will approximate 1 Gm of protein per pound of body weight. Some children who have been kept on a protein-free diet without results have shown marked improvement when a more liberal diet was given.

These children should be kept warm and warmly clad, and protected against bodily chilling. They should be protected, if possible, against infections, and exercise should not be allowed to the point of fatigue. As a matter of fact, if it is feasible, these children do better if they are sent to a warm climate during the cold winter months.

CHRONIC HYPERTROPHIC ARTHRITIS

To the Editor—A white man aged 43 came to me three years ago complaining of pain, redness and swelling in the right first metatarsal phalangeal joint. The roentgen diagnosis was hypertrophic arthritis. This has gradually progressed to the other foot, the hands, the cervical vertebrae, the wrists and the elbows in the order named. When first seen the patient had one nonvital tooth and a prostatitis manifested by swelling and tenderness and from 25 to 50 pus cells per high power field. The tooth was extracted and the prostate treated by diathermy and massage with gradual improvement. Since the marriage of the patient one year ago the pus cells have disappeared from the expressed secretion. A tonsillectomy was performed in June 1933. One year ago a general examination showed a persistent achlorhydria, blood nonprotein nitrogen 33.4, uric acid 3.4 and a basal metabolic rate of -3 per cent. The blood count, urinalysis and Wassermann reaction were negative. The man continues to have increasing involvement of the joints, muscular pains, a feeling of fatigue and gastric distress. He is a mental worker and improves immediately following vacations. Medication including salicylates, cinchophen, ammonium orthoiodoxybenzoate and hydrochloric acid gives little or no improvement. 1. Is there any other drug offering a good chance of success in an arthritis of this type? 2. What is the status of endocrine therapy? 3. Is induction of fever by mechanical means any more than palliative? 4. What are the comparative values of nonspecific protein therapy and autogenous vaccine (prepared for example from the prostatic secretion)? Please withhold name.

M D Michigan

ANSWER—1. There is no drug that can be used safely which offers much chance of success in treating arthritis of the type described. Elixir of phenobarbital in 4 cc. doses three times a day in addition to the salicylates has been found in some instances to bring about a more gratifying response than do the salicylates alone.

2. Endocrine therapy has proved of little value except in some cases in which the basal metabolic rate was definitely low.

3. The induction of fever by mechanical means often brings about a rather striking degree of improvement. In some patients this improvement has been maintained for long periods, but in most instances it has been temporary. It is doubtful whether the procedure justifies the risk that is entailed except in the case of relatively young persons who are organically sound and for whom the procedure may be repeated at regular intervals.

4. The question concerning the comparative value of nonspecific protein therapy and autogenous vaccine is one that is being widely discussed and on which there is no uniform agreement at the present time. The use of nonspecific protein causes a rise in body temperature that is quite comparable, both in its clinical aspect and in the results obtained, to the production of fever by mechanical means. Theoretically this improves the peripheral circulation and increases the metabolic processes of cells throughout the body. The autogenous vaccine is usually given in minute doses and causes little if any rise in the temperature of the body as a whole. The theory of this therapy would seem to be logical from the standpoint of raising the body's resistance to a specific organism provided the vaccine is obtained from organisms that may be reasonably suspected as being causative agents in the production of the disease itself. Repeated doses of such vaccines, together with the usual program for the care of these patients consisting of a diet low in carbohydrates and rich in vitamins C and D or to which these vitamins have been added in concentrated form and above everything else rest both at night and if possible, for an hour or more during the day, would seem to offer the best prognosis for ultimate recovery.

The fact that the patient reported improvement following a vacation is an almost uniform observation in patients with this type of arthritis. For that reason long periods of rest and if

possible, rest in a hospital or sanatorium where the program of care can be rigidly enforced, makes the prognosis better than is possible for those who for economic reasons have to work while undergoing treatment.

VASODILATORS IN HYPERTENSION

To the Editor—I write to ask why the standard vasodilators are not in good repute for the treatment of hypertension. Although their action is only temporary and palliative no satisfactory remedy for the condition exists. Since vasodilators in my experience act promptly and positively, it seems to me that their administration should be endorsed in selected cases. The ultimate results of hypertension are usually a diseased heart, sclerotic arteries or both. Hence is it not reasonable to assume that any measure that will lower the tension even for a few hours a day may help to postpone the final disaster? Concretely, I have a patient whose pressure falls from 180/100 to 162/84 on the administration of 2 grains (0.13 Gm) of sodium nitrite remaining at the lower point for two or three hours. During this period except sometimes for a slight headache the patient feels more comfortable. Am I not justified in alleviating his condition thus at least until something better comes along? Please omit name.

M D Illinois

ANSWER—The ill repute of the nitrite vasodilators for the treatment of hypertension has probably been exaggerated. It is a fundamental principle of sound therapeutics that the injured structures be given the maximum of rest. In hypertensive arterial disease the primary injury is the continuous hypertonia of the medial musculature of the arteriole. Arterial sedation, mild and long continued is an important part of the management of hypertension. To be of any permanent or curative value, such sedation must be continued for months.

The chief basis for criticism of the nitrite vasodilators is the transient nature of their pharmacologic effect. Of the soluble nitrites and nitrates (sodium nitrite, amyl nitrite, glyceryl trinitrate ['nitroglycerin'], erythrol tetranitrate, mannitol hexanitrate and spirits of ethyl nitrite) mannitol hexanitrate is said to have the most prolonged effect, the arterial tension usually remaining below previous levels for from five to six hours, whereas the effects of sodium nitrite ordinarily persist for from one to two hours. The extent of fall increases with the dosage, but the duration of action is not much influenced by the amount administered. After the initial violent drop in pressure that occurs on the inhalation of amyl nitrite, the tension may rise to levels in excess of the original reading.

Nitrites are not wholly innocuous. Large doses cause the formation of methemoglobin. Increased tolerance to the alkyl nitrates (especially to nitroglycerol) is acquired quickly, so that the dosage must be increased to obtain the usual effect. Avoidance of the drug for a few days usually restores the responsiveness. It is claimed that tolerance is not acquired to sodium nitrite or to erythrol tetranitrate. Excessive acute reduction of the arterial tension may cause relative hypotension with impairment of the cerebral circulation, especially if the hypertension has been long standing and arteriosclerosis has occurred. The dose of 0.13 Gm of sodium nitrite, although within the accepted range is a liberal one. It would appear more logical to give smaller doses more frequently, so that a milder effect might be maintained longer.

Because the fleeting nature of the vasodilator effects of these soluble compounds makes the induction of persistent and prolonged arterial sedation difficult, the use of a poorly soluble nitrate, which is reduced to nitrite by *B. coli*, has been suggested. Bismuth subnitrate, 0.6 Gm (10 grains) three times daily for weeks, has proved in the hands of a number of investigators to be a safe and often valuable adjunct in the management of hypertensive disease. The slow but continuous liberation of nitrite by the bacteria of the bowel generally maintains a continued mild vasodepressant effect. In the amounts indicated, bismuth subnitrate is nontoxic and rarely induces constipation. Its administration is safe. The thiocyanates, on the other hand, are more active arterial sedatives, but are too toxic to be safe. Although a few have doubted whether appreciable nitrite is obtained for the bismuth subnitrate reaction, it has recently been demonstrated that the nitrite content of the blood is distinctly increased by the injection of bismuth subnitrate as well as by sodium nitrite.

Aside from continued arterial sedation, it is imperative that therapy include correction of any causative factors that may be amenable to therapy. In the query nothing was stated concerning the probable or possible etiology of the hypertension in the case mentioned. Such factors as chronic plumbism, focal infections, dietary indiscretions, fatigue and worry and endocrine dyscrasias must be carefully searched for and, if feasible and safe, corrected. Curative therapeutics must include due consideration of etiology. Vasodilator drugs should be employed as auxiliaries.

ATROPHY OF MUSCLES AFTER NERVE INJURY

To the Editor—A man aged 24 was injured three years ago in an automobile accident. His left hand was amputated just above the wrist immediately after the accident. There were no other apparent injuries to the left extremity except minor abrasions of the skin. However in the three subsequent years there has been a progressive atrophy of the muscles about the left shoulder and arm, suggesting an injury to the left brachial plexus. On examination active movement of the left extremity is practically nil yet many of the groups of muscles react slightly to stimulation with the galvanic current. The patient has requested a higher amputation of the left extremity because of its uselessness and cumbersome. Is it possible to develop the muscles of the extremity by electrical stimulation after three years of progressive atrophy?

A. H. KIMMEL, M.D., Norwalk, Ohio

ANSWER—There is no conclusive evidence that atrophy of the muscles can be prevented by electrical stimulation. However, there is clinical evidence that the use of electrical stimulation by means of the galvanic current with the slow sinusoidal current will assist in preventing atrophy.

In this particular case a careful test should be made for the reaction of degeneration also a functional muscle test the same as that which is made for polymyositis to determine the strength of the various muscle groups. Both tests should be made in the lying position. If a Hubbard tank is available the patient should be placed in such a tank and the shoulder and elbow joints passively moved in all planes followed by passive therapeutic exercise for all muscle groups. Even though one is able to feel only faint contractions with the first endeavor one should persist in this type of work and proceed from the resistive to free movement and then to the resistive type. The patient should be dried well after being removed from the Hubbard tank. One should proceed with a light stroking massage for five or ten minutes and follow this with a mild slow sinusoidal current to a point of slowing contraction. This may not be more than three or four contractions just enough current being used to produce a mild contraction.

At the end of a month one should check again with a functional muscle test and an electrical test to determine whether the reaction of degeneration has decreased. If these tests show improvement one should continue with the treatment checking at the end of each month as to the further improvement being made. One need not consider amputation until after the use of treatment as outlined has proved of no value.

Examination in the lying position or in the Hubbard tank may prove that there is more movement than was originally thought.

URTICARIA WITH TRAUMA

To the Editor—A white man aged 42 who is a cornet player has suffered for the past three years from redness, swelling and itching of any part of his body that is used or rubbed. If he sits on a hard chair his buttocks are afflicted if he plays the cornet his hands and lips if he wears a hat and sweats his forehead. About once in four months and especially if he has a head cold he develops a generalized itchy maculopapular erythematous rash. All of these disappear spontaneously after one and one-half to two days. There is no history of allergy. General physical examination is negative. The Wassermann reaction is negative and the urine and nonprotein nitrogen are normal. Patch tests are negative except for rye egg pea and lima beans. Elimination of these has produced no result. Are all of his symptoms allergic? If not can you suggest a diagnosis? What further diagnostic procedures would you suggest? What is the present status of calcium, ephedrine and nitro hydrochloric acid in the treatment of allergy? Please omit name.

M. D., Connecticut

ANSWER—The most definite and constant element in the case cited is the precipitation of urticarial swellings at the point of mechanical irritation. Two possibilities are present. One is that an underlying chemical allergy, such as food sensitivity, is present and the trauma is the precipitating factor in the production of the lesion. The other possibility is that it is a pure physical sensitivity. Even though the latter is the case there is still no reason why it should not be regarded as 'allergic,' since allergy is essentially an abnormal response to a normal stimulus.

Pure physical allergy due to trauma is probably not common and it would be best to assume for the present that other causes are involved. Food sensitization should be considered first. Complete cutaneous tests should be made with foods and also inhalants such as epidermals and pollens. Intradermal tests are indicated if the scratch tests are negative. Food elimination trials are next in order if the tests are not conclusive. Patch tests in urticaria are of almost no value. They find their greatest sphere of usefulness in contact dermatitis. A search for foci of infection should be carefully made since a fair proportion of instances of urticaria and angioneurotic edema are caused by such chronic infections as may occur in the tonsils, sinuses, teeth, gallbladder and disturbed bowel function.

I further credence of such a possibility is evidenced in this case by the advent of acute exacerbations of urticaria following an acute infection of the respiratory tract.

In the event of failure of the foregoing a few other diagnostic and therapeutic procedures are available. Gastric analysis may show an achlorhydria or a hypochlorhydria. The use of dilute hydrochloric acid with meals with the possible addition of other enzymes may be of benefit. Occasionally the basal metabolism may be lowered calling for the use of thyroid extract. The serum calcium is rarely below normal. The administration of calcium salts is rarely of benefit although the use of para thyroid extract subcutaneously frequently controls the condition. A possible endocrine disturbance should be kept in mind. The possibility of nervous and psychic factors should not be neglected since they are at times even more important than the others.

It may be possible to help the patient by repeated attempts to desensitize the skin by mechanical trauma. This may be tried with the method of daily brisk rubs with a stiff brush, for example.

Ephedrine is of course of only temporary benefit and even then it usually does not give the results that one might expect. It is probably however the best and simplest symptomatic remedy, particularly in acute cases of urticaria. In other allergic conditions such as asthma and hay fever its action is more certain. In the main however ephedrine has not quite the degree of usefulness in allergic diseases that was expected a number of years ago. Nitrohydrochloric acid is probably no different than any other acid its action is probably that of favoring digestion. It may be useful occasionally in food allergy. In the hands of most men of wide experience in allergy it has been an almost universal failure in the treatment of hay fever.

LEUKOPENIA

To the Editor—I am a physician aged 28. After an exhaustive winter for three and one-half months I was bothered by periodic flare ups of marked weakness, easy fatigability and generalized muscle and joint pains without fever and with good nutrition. Exhaustive laboratory and roentgen tests for foci of infection were all negative and no clinical or physical pathologic condition was found except a white blood count of 5,200 and neutrophils 35 per cent with otherwise a normal smear. After perfect hygienic treatment there has been some slight improvement, but exacerbations every seven to ten days still occur with a fall of only 1,000 in the white blood count. I should much appreciate any suggestions for treatment of this condition. Have you heard of mild neutropenia alone causing these symptoms? Should penicillin be used? Would extract of yellow bone marrow be of use? What is the dosage and where can this product be procured? How about liver extract? One month ago I tried three 10 cc shots daily of penicillin with severe immediate and delayed reaction of malaise and fever. I am now trying 5 cc injections every other day. The results have been only questionable.

M. D., New York

ANSWER—The influence of physical or mental stress in precipitating the syndrome of relative granulopenia with malaise and exhaustion in individuals with a readily decompensated myelopoietic marrow function should be more widely appreciated. Proper rest and relaxation in the absence of other medication will frequently suffice to eliminate symptoms and restore the granulopoietic function to normal. In another physician with an identical history seen first four years ago the syndrome recurred three times. Nucleotide therapy invoked a remission the first two times but rest and a complete divorce from all professional responsibilities for a six week period was quite as effective the third time. There have been no symptoms and the white count has remained normal for the past two years the physician having resumed active practice. Therefore the first requisite under such circumstances is, temporarily, complete emotional and physical rest.

The degree of granulopenia is not necessarily proportional to the severity of symptoms. A relatively moderate neutropenia may be associated with marked subjective symptoms, while an extreme deficiency sometimes is unattended by the classic signs described by Schultz. In the absence of other demonstrable cause it is possible for the symptoms mentioned to be secondary to the relative neutropenia (35 per cent of 5,200 cells) cited though 1,800 granulocytes, if functionally mature and efficient, have more frequently than not been found to be above the critical level for the development of clinical symptoms. A continued search for some causative factor or factors outside the bone marrow is therefore indicated, as for example in the liver, spleen or lymph nodes.

Liver extract and yellow bone marrow are reported to have stimulated granulopoiesis in a limited number of patients but the rationale of this therapy is not yet clear. The marrow thus far used has been made up in capsules in the laboratories conducting the observations. Leukopenia secondary to megaloblastic anemia is a different entity.

blastic hyperplasia as in pernicious anemia, is, of course, automatically relieved by liver following the restoration of normal erythroblastic marrow, but this is not due to any direct effect on granulopoiesis. The late Roger Morris and his associates have reported a leukopoietic fraction in hog gastric juice capable of mobilizing granulocytes, but only a very limited number of observations have been made thus far and more fundamental studies under controlled conditions in animals must be awaited before this can be fully accepted.

The nucleotides have been administered daily to animals for as long as four months with a maintained elevation of granulocytes throughout this period. Clinically, however it has not been necessary to maintain the administration of nucleic acid products indefinitely.

The mechanism of hematopoiesis is so complex that it is essential to differentiate sharply between a great variety of leukopenic states of widely divergent etiology, if the problem of the individual patient is to be solved satisfactorily.

DIFFERENTIAL DIAGNOSIS IN ARTHRITIS OF SPINE

To the Editor—A white man aged 29, seen in May 1934 complained of pain in the sacro-iliac region and inability to stoop or get up from a stooping position. This complaint had been present for two days. The past history was negative except for gonorrheal urethritis ten years previously treated for one month and apparently cured and a fall from a pole in January 1933. He was working strapped to the pole when the strap broke and he slid down the pole about 20 feet striking the ground in a sitting position. At this time he made three visits to the doctor because of low back pain. This pain recurred at intervals but caused no loss of time from work until the onset of the present illness. Physical examination is negative except for extreme tenderness over both sacro-iliac joints considerable enlargement and tenderness of the prostate and almost pure pus expressed from the prostate gland. He was treated with sodium salicylate 10 grains (0.65 Gm.) every four hours strapping of the back hot baths and prostatic massage twice weekly. On this treatment he improved and the prostate returned to normal size but the prostatic fluid was still loaded with pus after four weeks treatment. At this time vaccine therapy was suggested and the patient did not return for further treatment. When next seen September 1 the back pain had recurred and pain and tenderness were present over the course of the left sciatic nerve. He was confined to bed. The prostate was of normal size but the fluid contained many pus cells. The urine contained mucus and pus cells. Roentgen examination September 4 with anterior posterior and lateral films showed no evidence of bone changes or traumatism of the spine. The patient was then referred to an orthopedist who placed him in a body cast for six weeks. This gave him complete relief from the symptoms. The prostatic massage was resumed and the fluid still contains many pus cells but they are much decreased, estimated at about 200 cells to each low power field. Roentgen examination about November 20 by another roentgenologist showed no definite evidence of arthritis of the lumbar spine or sacroiliac region. The articular facets between the fifth lumbar vertebra and the top of the sacrum were asymmetrically placed. All the inferior facets of the lumbar vertebrae were unequal on the two sides. The left inferior articular facet of the third lumbar vertebra and the right articular facet of the second lumbar vertebra were in two pieces. The roentgenologist believed that there was a slight anterior slipping of the body of the fifth lumbar vertebra on the top of the sacrum. The orthopedist does not agree with the roentgenologist regarding the slipping of the fifth lumbar vertebra. Prostatic smears were negative for gonococci. Pus cells and gram-negative cocci were found. The orthopedist is of the opinion that this disability is due entirely to the trauma incurred in the fall in January 1933. He bases this opinion partly on the fact that gonorrheal arthritis does not attack the spine or sacroiliac joints as a rule. I am of the opinion that this is an infectious process probably aggravated by the fall. Which opinion do you think is most likely true? Please omit name. MD Ohio

ANSWER—The important question involved is the question of trauma plus infection which can produce chronic arthritis. The injury localizes the focal infection in the spine. The spine may or may not have been involved before the trauma.

Trauma plus a chronic gonococcal infection can produce ankylosing arthritis involving the articular facets. As a matter of clinical experience gonococcal infection appears to have a predilection for the spine of young men.

If in the oblique roentgenographic projection the facets appear to be ankylosing one might assume an infectious etiologic factor, of which group the gonococcus is a classic example.

One may be dealing here with a nonspecific vesiculitis in which connection the use of Pregel's solution of iodine has been recommended. This treatment or any more appropriate treatment, should be administered by a competent urologist.

The question of spondylolisthesis should be determined by a careful examination of the relationship of the lumbar spine especially the fifth to the sacrum as presented in a lateral view. In this connection the so-called Ullman's line erected parallel with the anterior border of the first sacral segment should not cut off any of the inferior anterior portion of the fifth lumbar vertebra.

INITIAL INFECTION IN SYPHILIS

To the Editor—A woman aged 21, single presented herself to me with the chief complaint of nausea not related apparently to meals or to any particular time of day. General examination revealed no organic ailment, but the blood examination showed 4 plus Kahn and Wassermann reactions. The history was negative for any past primary or secondary lesions. Repeated laboratory tests of the blood merely verified the original result. Antisyphilitic treatment was begun in May 1933 and has been continued up to the present with but one month's interruption. From May 1933 to June 20 1933 she received eight injections of neoarsphenamine of 0.6 Gm each at weekly intervals. Then up to Oct 1 1933, twenty-four intramuscular injections were given of 2 cc of bismuth sodium tartrate. Then up to the present time the patient has received one injection of neoarsphenamine 0.6 Gm and one intramuscular injection of the bismuth preparation 2 cc each week. The total bismuth injections for the total period numbered about sixty-four and the total neoarsphenamine injections forty-two. Repeated blood tests have shown no change whatever with the exception of a slight reduction in the quantitative Kahn units. I should like expressions from you as to how this patient received her initial infection considering the fact that the past history was negative and considering also that the patient happened to be a very intelligent graduate nurse. Further, I should like to have an opinion on how the future course of treatment should be planned and what prognosis could be given as to cure. Please omit name. MD Missouri

ANSWER—History, particularly in the woman with syphilis is a conspicuously unsatisfactory way of determining the origin of a syphilitic infection. Even an intelligent graduate nurse has eight inches of genital tract wholly inaccessible to her own observation, and the observations of Anwyll-Davies tend to indicate that genitally acquired infections in women frequently begin with a cervical chancre. She may have been the victim of a misinterpreted extragenital infection masquerading as herpes tonsillitis or diphtheria. She may be the victim of a prenatal syphilitic infection and the inquirer's statement gives no particulars suggesting that this possibility had been investigated by clinical examination. If she has an acquired infection at least a spinal fluid examination should have been performed early in the course of the treatment described to determine whether or not the persistent positive blood serologic tests were features of a central nervous system involvement or not.

It is impossible to discuss further treatment or prognosis without the details of an adequate clinical examination and an examination of the spinal fluid. If the case turns out to be one of completely asymptomatic latency the treatment already given approximates and in fact exceeds the standard set by the Cooperative Clinical Group in this country for the management of asymptomatic latency. Should the patient desire to marry and have children the whole situation would be subject to reinterpretation in the light of adequate examination.

NUMBNESS OF FINGERS DURING PREGNANCY—DEATH IN COMA

To the Editor—1 I have a patient who has a numbness of the middle three fingers on her right hand. This is felt chiefly at night when she lies down. After the hand has become numb for a time it begins to ache. The most peculiar thing about it is the fact that she has it only when she is pregnant. It begins to bother her about the fourth month and then continues on through pregnancy. There are no foci and she is not a hysterical patient. She does have considerable gas otherwise the examination is negative. The pain does not respond to hot packs or to any of the salicylates. What would you recommend? 2 My next question concerns a woman aged 46 who died in coma the coma lasting seventy-two hours. She had had heart trouble for twenty years. She had a severe chronic interstitial nephritis but no hypertension. The phenol sulphophthalein test showed 40 per cent and her urea nitrogen was 20. There was no sugar in the urine on repeated examinations. She had no convulsions and at no time did she have Cheyne-Stokes respiration. Her final illness began with a heart attack. She became very weak unconscious and pale. I gave her some caffeine sodiohydroxide and she became conscious for a short time. At this time she thought she saw her husband who was away at the time. In a few hours she went into I would say a light coma. She opened her eyes at intervals and it appeared that she could see a person in her line of vision. I fed her through a nasal tube for about sixty-eight hours and catheterized her every twelve hours until she had incontinence. The last thirty hours her lungs filled with congestion which finally caused her death. What caused this coma? Her heart did not seem to give out. (She was completely digitized.) Please omit name. MD Nebraska

ANSWER—1 Numbness of the middle three fingers does not correspond to the distribution of the peripheral nerves. The fact that the numbness comes only with the patient in the recumbent position suggests that pressure or posture may be a factor. Since the complaint is present only during pregnancy, however the diagnosis is complicated. Numbness or paresthesia is usually an early symptom of peripheral neuritis, of combined sclerosis in pernicious anemia or of cerebral arteriosclerosis. In many cases no organic cause is found. Neuritis in pregnancy

has been described, but the fact that in this case numbness follows no nerve distribution and is not associated with pain seems to eliminate this etiologic factor. Deficiencies in calcium metabolism during pregnancy, with neuromuscular disturbances are not uncommon. Administration of calcium and viosterol could be tried. It would be well to determine whether the pulsations are normal in the peripheral arteries and whether there is diminished circulation during the periods of numbness. This can be determined by the presence of reduced temperature of the affected fingers. The fact that this condition has persisted for a period of years without evidence of primary disease or serious sequelae would rather incline one to believe that it is an expression of a functional disorder rather than any organic complaint. No special treatment seems indicated if primary disease is not found. Relief of the anxiety associated with the complaint is often effective.

2. The data indicate that renal function was fairly adequate and was not the basis of the coma. The patient's age (46 years) suggests two possible causes of coma and death: (1) cerebral embolism, if valvular heart disease was present, or (2) some primary cerebral disease, such as thrombosis of an artery or acute encephalitis. Coma seemed to predominate in the terminal picture. This is rare in coronary thrombosis or in acute cardiac death. The absence of precordial pain is against this diagnosis. The usual causes of coma of renal or diabetic origin or from drug poisoning seem in this case to be ruled out. The most rational explanation is some cerebral basis, probably encephalitis.

CONVULSIVE SEIZURES IN INFANCY

To the Editor—A boy baby aged 5½ months, has had convulsive seizures for one month. The spells last usually not over one minute and may be as frequent as from three to eight attacks in twenty-four hours with periods of freedom from attacks for as long as ten days. A typical spell is ushered in by a sort of overexcited period of a few seconds followed by an expression of distress, rapid shallow respirations, apparent loss of consciousness (variable) lasting half a minute then a muscular convulsion of the whole body lasting a few seconds and then relaxation, drowsiness and fretfulness. The parents can recognize the first symptoms and the procedure can be stopped by giving the child a warm bath. The personal history is that of a normal spontaneous full term birth, normal gain in weight and no other diseases. The convulsions have no effect on the gain in weight; there is no fever. Reclining usually follows an attack. The child is on breast milk, orange juice, halibut liver oil and cereals. Physical examination is entirely negative. Including the facialis symptoms of Chvostek. Two lower incisor teeth are about to erupt. The urine was strongly alkaline and was acidified but the spells continued. The child's older brother had what is described as the same condition from the age of 3½ to 11½ months. He was taken to many specialists and clinics and no cause ever was found. He recovered spontaneously and now is normal at the age of 4 years. There is no history of convulsions on either side of the family for three generations. The baby's mother has been in the habit of giving him sodium bicarbonate water several times a day on general principles. I had that practice stopped and administered very weak hydrochloric acid water until the urine became acid. This apparently had no effect on the convulsions but it has been only two weeks since this was accomplished. The child has a tendency to constipation. Do you think alkalosis can explain these attacks? What prognosis do you offer? A recent telephone call advises me that convulsions have not occurred for four days.

EVAN B. HUMZ, M.D., Menard, Texas

ANSWER.—The most frequent causes of repeated convulsions at the fifth month of life are tetany, cerebral hemorrhage, acute infections and epilepsy. Other causes, such as tumor or abscess of the brain, imperfect cerebral development and hypoglycemia should also be included. Convulsions in infancy during the first three or four months of life are usually organic in nature and are due to increased cerebral pressure from hemorrhage or injury to the brain, or to asphyxia from atelectasis. In the age group after the first few months of life up to 2 years of age, tetany is the most common cause of convulsions.

In the case in question, although the Chvostek sign is negative, further examinations, such as Trousseau's symptom, the altered electrical reaction described by Erb, and a chemical blood test to determine whether a lowered blood calcium content exists, should be undertaken to rule out tetany as a cause of the convulsions. To rule out other organic causes, examination of the spinal fluid and eyegrounds should be made, to determine whether increased intracranial pressure from tumor, abscess, traumatic injury or maldevelopment of the brain might be the cause of the convulsions. A blood sugar examination would reveal the hypoglycemic origin of the convulsions.

A severe degree of alkalosis might be the cause of the convulsions, though other symptoms, as nausea, vomiting and stupor, are absent. While the urine may be alkaline in alkalosis it need not be so. Laboratory examination of the blood, to determine whether the carbon dioxide content and pH are increased, will show whether a state of alkalosis exists.

Finally, if all organic causes are ruled out, petit mal or minor epilepsy must be considered as a cause of the convul-

sions. These attacks may be of short or momentary duration, accompanied by muscular twitching, and may recur several times a day, or they may occur at longer intervals. The prognosis depends on the diagnosis in such a case. If the convulsions are due to organic brain disease, the extent and nature of the involvement would decide the prognosis. If the convulsions are due to tetany, suitable treatment would offer a cure. The question states that the infant is receiving halibut liver oil. This substance contains considerable amounts of vitamin A but is rather low in vitamin D. A sufficient amount of vitamin D in the diet would insure against a recurrence of tetany. Epileptic convulsions can be controlled, and perhaps outgrown in later childhood.

CHRONIC POSTERIOR URETHRITIS

To the Editor—This may be an example of how not to treat gonorrhea, but perhaps you can give me some advice. The patient is a white man aged 45 divorced. Gonorrhea first occurred at the age of 21. The present infection occurred in October 1933. I saw him about a week after the discharge began and made a diagnosis of acute posterior urethritis. I gave him a lysocyanus polysaccharum citrate prescription to be alternated with methenamine. Acetylsalicylic acid was used for pain. He was advised to go to bed and use hot sitz baths but because of economic and general living conditions could not do this. His discharge and painful urination persisted about two months and then almost cleared. In December 1933 he had three abscessed teeth extracted. Following this the discharge and pain returned in extreme form. A generalized edema developed and an epididymitis. Drugs of every sort were tried without any relief. Shortly afterward he began to have bladder spasms and to pass varying quantities of pure blood at the end of urination. I took him to a urologist who advised irrigations followed later by prostatic massage. Irrigations were tried but caused an increase in the severity of the symptoms. He was hospitalized for some time. Cystoscopic examination was attempted but failed. Guinea pig inoculations showed no tuberculosis although his discharge diagnosis was tuberculosis of the prostate. He is still having the bladder spasms, from two to ten a day. He urinates about every fifteen minutes and passes occasional blood clots. The spasms are relieved more quickly if he can pass a clot. Recently he passed about 8 ounces of blood through the urethra and an undetermined quantity by rectum. Prostatic examination is unsatisfactory owing to the extreme pain. Smears of pus show large numbers of gonococci and cocci resembling staphylococci. The only drug that will give any relief is morphine and that is not very satisfactory. I have used vaccines with questionable results. Catharsis relieves some probably through reduced urinary output. Is there any chance that foreign protein injections may aid? What courses of treatment would you suggest? Please omit name.

M. D. Indiana

ANSWER.—It is probable from this case history that one is dealing with a chronic posterior urethritis, probably entirely secondary to a specific prostatic vesiculitis. One should suspect bullous edema or polyp formation in the posterior urethra or on the vesical neck when there are bladder spasms and hematuria.

In spite of the severe symptoms and the gonorrheal infection, it is imperative to do cysto-urethroscopy in order to make a proper diagnosis. This would also exclude the possibility of double lesions, such as cancer and gonorrhea or contracture of the vesical neck and gonorrhea. If the bladder and its outlet are without pathologic change, ureteral catheterization should be done to exclude chronic gonococcal pyelonephritis or pyonephrosis and other kidney lesions. Cystoscopy could be done easily by means of caudal injection of 20 cc of 1:1,000 nupercaine solution.

One can use cystoscopic fulguration for inflammatory tissue tags, polyps or bullous edema. Following this procedure the patient should take one 10 minim (0.6 cc.) capsule of santal oil after each meal and at bedtime. He should take a ten minute sitz bath every morning and evening. His fluid intake should be moderate. A scrotal supporter should be worn. It is advisable to have the patient inject the anterior urethra every morning and evening with 5 per cent neosivol solution, holding the medicine in the urethra for five minutes.

One week of this management should improve the patient enough to allow a moderate stripping of the seminal vesicles and prostate gland, after which a 5 per cent solution of mild silver protein should be instilled into the bladder, posterior urethra and anterior urethra by means of a small Guyon instillator. This procedure should be carried out every five days. About the third week, one should begin to alternate the passage of urethral sounds with the massages every five days. There would be little value in the use of foreign protein.

If improvement has not taken place after a proper period of the foregoing management, one should consider bilateral vasostomy with injection of 5 per cent collargol solution into the seminal vesicles to help rid them of infection.

BRONCHIAL ASTHMA

To the Editor—I have under my care a case of bronchial asthma in a young unmarried woman who has had severe attacks only on visits to Boston, which usually occur in the last week in December. Such attacks have occurred on visits as early as November and as late as February. Her home is in Washington D C, where she has never had an attack of asthma. Her visits to Boston last about a week during which period she is severely ill but recovers within two days after leaving. The patient makes visits to the same area every July but has only a slight attack at such times. Close questioning has elicited no significant information with regard to animal contacts food bedding house dust and so on. Please advise what allergens should be used in skin tests. Please omit name.
M D, District of Columbia

ANSWER.—The fact that the attacks of asthma come only in the winter months rules out pollen sensitivity. This leaves for consideration only foods, epidermal substances, drugs and miscellaneous antigens, such as orris root, cottonseed and flaxseed. Bacterial allergy is possible but unlikely.

It is suggested that the history be rechecked, especially with relation to exposure to animals either at the home in Boston or in the homes of friends in that city. Sufficient contact may be had by visiting such homes or by carrying animal hair and dander from houses in which animals live. In addition, any unusual foods should be noted, any unusual drugs should be checked, as amidopyrine, acetylsalicylic acid and quinine, one should look for exposure to unusual cosmetics, as in beauty parlor treatments. The pillows and mattress should be examined to see whether they contain hair or feathers. Because of the frequency of sensitivity to hair, feathers, cottonseed and dust of mattresses and pillows it would be safer to cover these with light rubber sheeting, sewed in securely.

Complete skin tests should be carried out, including all known antigens. It is unwise to do partial testing, as the antigens omitted may turn out to be the important ones.

It is suggested also that the bedroom in Boston be thoroughly gone over with a vacuum cleaner so as to eliminate as much dust as possible.

INCONTINENT AND INVOLUNTARY

To the Editor—Please give me the proper words to use in describing involuntary action of the bowels and bladder. Is incontinent or involuntary good or are there better terms?

J L PRITCHARD M D San Jose Calif

ANSWER.—The word "involuntary" refers to an act that is performed independently of the will. The word "incontinent" is used when a patient is unable to restrain natural evacuations, normally all persons are continent because they can control the action of the bladder or the bowel. The patient is incontinent because he is unable to restrain his natural evacuations. The action on the part of the bladder or bowel is involuntary. The patient is incontinent.

HAZARD OF INHALING DUST

To the Editor—Does the dust inhaled in the grinding of casein hardened with formaldehyde constitute a known industrial hazard?

CHARLES B F GIBBS M D, Rochester N Y

ANSWER.—The hazard of inhaling such dust is from traces of the formaldehyde that has not reacted with the casein and the effect is typical of that from low concentrations of formaldehyde vapor. The buffing, polishing and grinding of these casein formaldehyde condensation products should be done under adequate exhausts that prevent the dissemination of the formaldehyde vapors.

CASTOR OIL AFTER SANTONIN

To the Editor—The staff here disagrees as to the advisability of using castor oil immediately after the use of santonin. Some claim that the use of oil makes santonin toxic. Please advise. Kindly omit name.

M D Georgia

ANSWER.—Castor oil does not increase the absorption of santonin. The castor oil may be given immediately after the santonin or even combined with it.

ALKALINE RESIDUE DIET

To the Editor—What articles of diet can be used to make an acid urine alkaline an alkaline urine acid? Please use initials only.

M D Minneota

ANSWER.—Articles of diet that leave an alkaline residue are fruits (except cranberries, prunes and plums) vegetables beans peas and milk. Those which are acid producing are meats fish eggs cereals and the fruits mentioned as exceptions.

Alabama January Examination

Dr J N Baker, secretary, Alabama State Board of Medical Examiners, reports the written examination held at Montgomery, Jan 8-10, 1935. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Ten candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
University of Colorado School of Medicine		(1934)	84.2
Rush Medical College		(1934)	88.7
Tulane University of Louisiana School of Medicine		(1934)	91.3*
83 85 8 89 2		(1934)	82.7
Johns Hopkins University School of Medicine		(1928)	85.8
Duke University School of Medicine		(1933)	86.3
University of Pennsylvania School of Medicine		(1934)	88.4

* This applicant has received a four-year certificate and will receive an M.D. degree on completion of internship.

Arizona Reciprocity Report

Dr J H Patterson, secretary, Arizona State Board of Medical Examiners, reports two physicians licensed by reciprocity at the meeting held in Phoenix, Jan 23, 1935. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Rush Medical College		(1932)	Illinois
Dalhousie University Faculty of Medicine		(1928)	Nova Scotia

Ohio Reciprocity and Endorsement Report

Dr H M Platter, secretary, Ohio State Medical Board, reports 20 physicians licensed by reciprocity and 2 physicians licensed by endorsement at the meeting held Jan 8 1935. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Howard University College of Medicine		(1933)	Missouri
Loyola University School of Medicine		(1932)	Illinois
Indiana University School of Medicine		(1909)	Indiana

Universität Rostock Medizinische Fakultät Germany		(1919)	N Dakota

Book Notices

Surgical Diseases of the Chest By Ervarts Ambrose Graham A.B. M.D. F.A.C.S. Professor of Surgery Washington University School of Medicine St Louis Jacob Jesso Singer M.D. F.A.C.P. Associate Professor of Clinical Medicine Washington University School of Medicine St Louis and Harry C Ballou M.D. C.M. F.A.C.S. Cloth Price \$1.50. 1p 1070 with 637 Illustrations Philadelphia Lea & Febiger 1935

For some time physicians have been eagerly awaiting the appearance of this book. They have been looking forward to it for two reasons. In the first place, there has been a definite need for a book on surgical diseases of the chest in which the medical aspect is emphasized. In the second place, a book by these authors, who have themselves been in the front line of the advance in the progress of chest surgery, should be a good one. Now that the book is available, there is no disappointment on either count. From the first paragraph of the introduction to the last chapter, which describes the set up of the Barnes Hospital Chest Clinic, the book definitely deals with surgical diseases of the chest from the clinical point of view. This does not mean that operative technique and proceedings are not fully described but does mean that physiology, pathology, diagnosis and other factors which every good surgeon must take into account in acquiring a well rounded knowledge of the subject are given ample consideration.

As might be expected, the experimental side of many of the problems in chest surgery has been dealt with, sometimes at length, sometimes briefly. Many of the chapters are actually monographs on the subject rather than the usual subdivision of most textbooks. The text is profusely illustrated not only with diagrams, photographs and roentgenograms but also with case histories and records of patients. In spite of the addition of many subjects often omitted from the telegraphic form of school books, the subject matter is most accessible. This is due to the excellent indexing and the boldface captions that introduce the various paragraphs. The reader who is seeking for some particular phase of any subject can tell at a glance whether or not this or that paragraph will give him the information he wants.

Helen Lamb, chief anesthetist to the Barnes Hospital, has written the pages devoted to endotracheal and endopharyngeal anesthesia.

David H Ballou lecturer on otolaryngology at McGill University Faculty of Medicine, has written chapters having to do with bronchoscopy. Ralph Matson, whose contributions in the field of intrapleural pneumolysis have been noteworthy, has presented this subject, while Dr Roy Matson, since deceased, has written the chapter on oleothorax. A large bibliography on each subject has been appended.

The authors in the preface state that their aim has been to prepare a book "which should appeal both to the internist and to the surgeon. The appeal to the former seems to be particularly desirable because even now there is an insufficient appreciation of the accomplishment of thoracic surgery and of the help in many conditions which a surgical attack offers." They have well accomplished their purpose. This book will be used as the standard text and reference work in surgical diseases of the chest in all medical schools.

Das Extremitäten Thorax und Partiel Elektrokardiogramm des Menschen. Eine vergleichende Studie. Von Prof Dr Franz Maximilian Groedel Direktor des Willkomm G Kerckhoff Herzerforschungsinstituts zu Bad Nauheim. Band I Text Band II 200 Tafeln. Cloth Pp 338 with 334 Illustrations 200 plates Dresden & Leipzig Theodor Steinkopff 1934

In this monograph the author summarizes his experiences with electrocardiography, especially the newer angles with which he and his associates at Bad Nauheim have recently concerned themselves. It is a highly involved presentation, suited only to the advanced scholar in electrocardiography. This being the case, many of the simple expositions employed by the author in connecting the various portions of the book are unnecessary. The major theme of the presentation is the author's attempt to prove that he has finally been able to determine the true partial electrocardiogram of the right side and of the left side of the heart. This is based on the erroneous belief that the two sides can be conceived as being separated by a dielectric. The right partial electrocardiogram he obtains

by connecting the negative terminal to the right arm and the positive just to the left of the sternum at its midpoint. The left partial electrocardiogram he obtains by connecting the positive terminal to the chest in the left axillary line at the level of the xiphoid process. The evidence presented to show that these leads have finally solved the so-called partial electrocardiogram of each heart is far from convincing. The author's wish seems to be father to the proof. The most valuable part of the book is the author's succinct summary of the more interesting developments in the fundamental studies of the electrical field which his associates have carried out and published. The author errs seriously in ignoring or in dismissing casually the recent fundamental developments that have come from several laboratories in this country, most of which antedate the work presented in the monograph. His casual dismissal of the so-called fourth lead as practiced in this country is unwarranted. In fact, his curves will be useful in advancing the practical use of precordial leads. His curves are the inverse image of those published with precordial leads in this country. He presents a collection of carefully coordinated electrocardiograms obtained from these precordial leads, together with the classic three leads, analyzed x-ray projection of the heart and brief case histories obtained in a large number of normal subjects and patients with heart disease. The present tendency growing among experimental cardiologists to return to the original concept of Waller on the nature of the electrical field and to drop the classic interpretation of the Einthoven triangle is well exemplified in this book. The unwarranted deductions included can be readily excused on the basis that this work was brought to an abrupt close by exigencies over which the author had no control. For the investigator in this field the original protocols will be extremely useful, but the reader should not be swayed by the interpretations as far as the author carries them.

Memoirs of a Small Town Surgeon By John Brooks Wheeler A.B. M.D. Sc.D. Cloth Price \$3 Pp 336 with 4 illustrations New York Frederick A. Stokes Company 1935

This is an account of a fortunate life. John Brooks Wheeler got his college education at the University of Vermont. He graduated from Harvard Medical School in 1879, had an internship in the Massachusetts General Hospital, and, preferring to live in a small city rather than a large one, went back to his home, Burlington, Vt., where he spent a long professional life. In addition to having the attractions of a prosperous town of 20,000 people, beautifully situated in the hills of Vermont, it had the professional advantages of having a hospital—the first between Albany and Montreal—and the Medical School of the University of Vermont.

The book is agreeable reading from beginning to end. The author gives an instructive discussion of medical education in the late seventies, when Harvard and the Chicago Medical College were the only schools in the country having a graded course or a three years compulsory course. He reviews the condition of surgery with the eyes of one who has seen the evolution of modern surgical technique and he describes in retrospect the surgery of the late seventies and eighties when the older generation of surgeons were struggling in a half-hearted or awkward way to practice antiseptic surgery. He gives an interesting picture of the Harvard Medical School of his day and of the notables on its faculty, Oliver Wendell Holmes, Henry P. Bowditch, Henry J. Bigelow, David W. Cheever, Reginald W. Fitz and others. One gets the impression that he regarded Fitz as perhaps the leading physician in the faculty. Wheeler spent eighteen months at the Massachusetts General Hospital and he gives an interesting and pleasing account of the hospital in those days. He saw its many defects but on the whole he shows that it was a well conducted institution, with high ideals, and was a fine place for interns. He was on the surgical service and Bigelow and Charles B. Porter were the most prominent surgeons. He regards Porter as one of the two or three best surgical operators that he has ever seen, and in all ways an able surgeon. Bigelow was the notable surgeon in New England and among the most famous in the country at that time. Wheeler paints Bigelow as a very able surgeon, he uses the word 'genius' in connection with him which probably is not deserved. Bigelow was of

the pompous old great surgeon type, and what with his vanity, manifest ostentation, arrogance and self importance does not appear altogether as a pleasant human character.

Then Wheeler went to Europe for a year and a half, where he had the familiar and useful experience of American students who were fortunate enough to go to Vienna at that time. He gives pleasant glimpses of the life of the American students in Vienna of the postgraduate training they got there and of the personalities. He then returned to Burlington to practice. He gives an interesting discussion, with reasons that would appeal to a wise man, for settling in a smaller city such as Burlington.

The second half of the book is devoted to his experiences as a surgeon for fifty years spent in a busy and useful practice. It is the familiar story heard so often from other able men similarly situated, and Wheeler tells it well. As a physician reads it he gets the feeling of pride in his profession that is always stimulated by the accounts of such careers. Wheeler has led a singularly fortunate life. His youth in medicine was spent in wholesome and happy surroundings, and his later career has been similarly circumstanced. He has been able, effective and successful. In retrospect he looks at his life with wisdom and optimism, and it makes his account instructive and refreshing reading.

Sang et organes hématopoiétiques Par A. Touraine médecin des hôpitaux de Paris Paper Price 30 francs Pp 275 with 21 illustrations Paris Masson & Cie 1934

This volume is one of a series on the subject of diagnosis and treatment of the various specialties in medicine. The purpose of the work is to develop enough fundamental information so that the novice will clearly understand the methods by which diseases are recognized and rationally treated. Hematology lends itself nicely to this purpose since, through the study of the blood-forming organs, the general reactions of the body against disease may be evaluated. The work is presented in a clear and simple manner and is addressed particularly to the medical student. The author has made a definite effort to simplify the controversial terminology in the belief that it is often this phase of the subject that discourages beginners. A concise but thorough discussion of normal blood and its formation is presented with later treatment of blood in pathologic states. The book is well organized and should be of great value to those interested in a short account of the elemental aspects of diseases of the hematopoietic organs and the practical aspects of modern clinical and therapeutic methods in hematology.

Illustrative Electrocardiography By Joseph H. Bainton, A.B. M.D. Attending Physician and Chief of the Cardiac Clinic, Morrisania City Hospital, New York City and Julius Burstein, A.B. M.D. Associate Electrocardiographer, Morrisania City Hospital, New York City. Cloth Price \$5 Pp 258 with 100 illustrations New York & London D. Appleton Century Company 1935

This work is an atlas of electrocardiograms. A total of 155 are shown, well reproduced at a reduction to two thirds in size. The only text is a short but concise description accompanying each tracing. The more frequent abnormalities are shown in the most detail, so that greatest emphasis comes on conduction abnormalities and changes in the T waves. A valuable section shows serial tracings made during acute infections, as pneumonia, typhoid and rheumatism. Also serial tracings show the changes due to digitalis action in a variety of abnormalities. Serial tracings after coronary occlusion are shown in detail. There is no mention of technical or mathematical concepts. No controversial material is included. The common sense view of the authors is well exemplified in this paragraph: "The record, therefore, represents an activity which depicts the variations of normal or pathological physiology and is never direct evidence of structural defect."

It has been found that characteristic changes occur in the electrocardiogram with fair regularity in the presence of certain definite structural lesions and rarely with any other lesion. A definite pathological diagnosis, however, is justified only in the presence of additional evidence obtained from the history and the physical signs. The book is of much value in assisting the detailed study of tracings, yet it constantly sends the physician back to the study of the patient for the last word.

Pflanzliche Therapie. Eine Anleitung mit Beispielen zur Rezeptur
Von Dr. Ernst Meyer, Oberarzt der Inneren Abteilung des städtischen
Krankenhauses, Berlin Spandau. Boards. Price, 4.80 marks. 1 p. 202
Leipzig: Georg Thieme, 1935.

This is evidence of the recent tendency in Germany to return to the use and study of the herb remedies of the forefathers, with special emphasis on the native herbs. The therapeutic use of herbs, which is being dignified by the special term "phytotherapy," is to be rescued and put into the place it held before the "victorious march of modern chemistry and pharmacology." One cannot charge the author with being narrow or prejudiced, for in addition to the generally accepted and fairly well understood drugs of vegetable origin he overwhelms the reader with mention of dozens of herb products that are claimed to have valuable therapeutic effects. To show that he is not prejudiced he throws in for good measure the names of dozens of remedies employed by the "biochemist" and the homeopath. The scientific value of the book may be measured by the prescription part, which in addition to remedies of established action advises for the treatment of tuberculosis a tea composed of five different herbs, for kidney stone, a tea composed of four different herbs, which is also the number of different herbs recommended for hematuria and uremia. Compound herb remedies also are recommended for the treatment of chronic arthritis, gastric catarrh and liver disease. The author rescues from medical oblivion the "spring herb cures," presumably for "spring fever." He has more or less complex teas that he recommends for exophthalmic goiter and others for diabetes mellitus. He seems convinced that herb therapy is of great value in neuroses, to judge from the number and complexity of prescriptions recommended. Fortunately, he advises his herb teas in syphilis and gonorrhea merely as adjuncts to other treatment. Even for leukorrhea he advises internal treatment with polypharmaceutic teas (1) and all this is a result of his studies of books on the subject and personal clinical experience of four years (1). Evidently the author who is the chief physician of the internal medicine department of the City Hospital Berlin-Spandau, believes like a number of other medical men now prominent in Germany in progress by retrospection. It is to be hoped that out of this uncritical resurrection of ancient remedies at least one of real value may arise.

The Crippled and the Disabled. Rehabilitation of the Physically Handicapped in the United States. By Henry H. Kessler. Cloth. Price \$4. Pp. 337. New York: Columbia University Press, 1935.

The problem of the care of the crippled and the disabled in the United States involves more than the mere physical rehabilitation of those who can be restored to functional independence through the application of modern medical principles and surgical skill. Education of the public is advised to make the average citizen more cripple conscious and to break down the barriers of psychologic and economic prejudice, which, the author shows, are based on "superstition, misunderstanding and false concepts of capacity to work." There is need for just such a discussion and presentation of facts as are contained in this book. Patients who have been rehabilitated are frequently refused an opportunity of earning their own living even though they may have excellent mental and ample physical capacities for work. Such patients are discouraged by the unfair treatment they have received at the hands of employers who may have contributed to the support of the same hospitals where the cripple received treatment but are unwilling to change a social attitude or legal limitation that prevents the crippled and disabled from earning a livelihood at tasks that he may be able to perform as well as any normal person. Dr. Kessler has handled his subject matter intelligently sympathetically and forcefully. He has called attention to the crippled representatives of professional and industrial groups who have achieved fame. A careful analysis of the efficiency of the physically disabled as compared to the normal employees of large industrial concerns which are willing to employ people of this class, including the Ford Motor Company, has led to the conclusion that the physically handicapped group are "as productive as normal workers, or even more so." Dr. Kessler has given an analysis of the problem from various angles, including that of the child cripple, the military, industrial and chronic disabled,

and the blind deaf and dumb. The suggested remedy calls for better education of the public with regard to the problem itself, state and national legislation, and better cooperation between various agencies, public and private. This book should be of interest and of genuine help as a source of information for all who are socially minded and especially for those who are concerned with the question of the welfare of the large group of both children and adults who are physically disabled and who must be placed in a position for earning their own living or become public burdens for life. The book is recommended to physicians, sociologists and economists and should be of value to every governor of a state, legislator or congressman who is truly concerned with the present and future welfare of his state and country.

Traité de climatologie. Biologique et médicale. Publié sous la direction de M. l'Écuyer, professeur d'hydrologie thérapeutique et de climatologie à la Faculté de médecine de Lyon. Secrétaire de la rédaction: M. l'Écuyer, assistant d'hydrologie thérapeutique et de climatologie à la Faculté de médecine de Lyon et B. Van der Flst, docteur ès lettres, conférencier de l'Institut Catholique de Paris. Préface du Pr. d'Arsonval. In Three Volumes. Paper. Price 330 francs per set. Pp. 2664 with 453 illustrations. Paris: Masson & Cie, 1934.

The foundation of nine chairs of climatology in French medical schools in the last ten years indicates the importance given to this subject in France. Voltaire expressed his belief that "the earth and the atmosphere influenced all the products of nature, beginning with man and ending with mushrooms." And Montesquieu had realized that different climates had produced different customs and diverse laws. Perusal of these three splendid and complete volumes on climatology reflects the neglect of this important subject in this country. Three divisions can be distinguished in this treatise. The first on meteorology, physiology and ecology, the second giving a detailed description of the climate of different countries, the third giving clinical aspects of climatic treatment.

The meteorological and physiologic part is generally good and it is convenient to find all such information so collected. The biologic importance of saturation deficit and evaporation rates is stressed, as opposed to the measurement of relative humidity, which is usually given in meteorological data. An interesting discussion is given of the influence of low atmospheric pressure on the organism, but it seems unnecessary to repeat this discussion by five different authors in five different chapters. While these five authors arrive at substantially the same conclusions, two different authors arrive at diametrically opposite conclusions with regard to tropical climates. One holds that a tropical climate is not in itself harmful, but only the tropical diseases, while the other believes that such climate itself has a bad effect on the white race.

While all components of the atmosphere including radioactive gases, products of combustion and bacteria are amply discussed, the presence of pollen in the air is barely mentioned. The extensive American work on pollen distribution during various seasons and in different places is completely ignored. Hay fever and asthma are known to be responsive to climatic treatment, yet in the chapter on "phytoclimatology" no attention is paid to the distribution of plants causing hay fever.

Most of the articles are written by men who are recognized as authorities in their fields, and high standards of scientific accuracy are set. The article by a Russian author on the treatment of tuberculosis by positive and negative ionization of the air by an apparatus of his own invention falls perhaps a little below the standard set by the rest of this monumental work. The same author, in another chapter, tries to explain the succession of liberal and conservative ministries in Great Britain during the nineteenth century by the sunspot activities. The same sun spots are also blamed for alleged influenza epidemics and for almost all social activity since 500 B. C. Such a reductio ad absurdum of the theory of sun spot cycles is hardly to be taken seriously.

The most valuable part of the work is the admirable description of the local climates of France. For every climatological station one finds monthly averages of temperature, rainfall, wind direction and wind velocity, together with a discussion of other advantages. This discussion fills about 500 pages, while the climate of the rest of Europe is described in 180 pages. The climate of the United States is given nine pages. The White Mountains and parts of New Hampshire and Maine are mentioned as resorts for hay fever patients. The Adirondacks and Colorado are referred to for their fame in the cure of

tuberculosis In connection with the former, Trudeau is said to have had a French-Canadian ancestry, whereas his father was of New Orleans Huguenot stock In regard to the latter, "the sources of the Colorado" probably refers to Colorado Springs

All altitudes are given both in feet and in meters but the author chose 32.25 centimeters as the equivalent of a foot, while 30.48 is the correct value

Credit is given Davos investigators for the discovery of the increase of lymphocytes in the blood at altitudes, whereas Webb and Williams in this country were the first to make this observation

These, however, are minor criticisms and the work is invaluable for the enormous amount of information it contains A glance will tell what weather to expect in a given month at Madeira, Athens or Nice Physicians who have patients going to Europe and especially to France will be well rewarded for consulting this truly great work

Hachlich Herba de folle at da robe Par Pascal Brotteaux docteur on pharmacie Paper Price 20 francs Pp 103 Paris Les Editions VEGA 1934

This treatise on cannabis sativa is timely in view of the interest being taken in the widespread and apparently increasing abuse of cannabis throughout the world The book is based largely on studies made in northern Africa and in the Near East, but those in the United States interested in investigating the use of marijuana in North America will find in it data useful to them The author uses the word "hashish" not in its restricted meaning as indicating the particular preparation of cannabis resin called by this name in Egypt, Persia and Turkey but as a general term for all preparations made from cannabis sativa, including not only galenic preparations but also hashish, esrar, madjun, ganja, takruri, kif dagga djamba and bhang He does not treat at any length of the form in which cannabis is used as an addiction drug in the United States and Canada, i e, marijuana or the dried leaves and resin of flowering tops of Indian hemp that is smoked in the form of cigarettes The book reviews the subject first from the historical point of view and then, separately, in respect of botany and materia medica, chemistry pharmacodynamics and pharmacology Methods of treating addiction to cannabis are not discussed, although the subject of mental disorders associated with its abuse is touched on The book contains a complete bibliography but is without an index It contains a description of the sensations experienced under cannabis intoxication and of the physical and psychologic effects produced by intoxication The effect of cannabis intoxication leads the author to conclude that the drug has some value in revealing the content of the subconscious mind As to its therapeutic uses the author concludes that exact knowledge is limited and that it would be desirable to restudy the subject with particular reference to its possible use in psychotherapy

Traité de physiologie normale et pathologique Publié sous la direction de C H Roger professeur honoraire de physiologie à la Faculté de médecine de Paris et Léon Binet professeur de physiologie à la Faculté de médecine de Paris Tome V Respiration Par MM Léon Binet L Dautrebande H Hermann C Heymans et Pierre Thomas Boards Price 100 francs Pp 474 with illustrations Paris Masson & Cie 1934

In addition to the usual chapters on the physiology of respiration, this useful volume includes good sections on basal metabolism (forty-nine pages), on therapeutics of respiration (fifty-seven pages), and on nonrespiratory lung functions The chapter on the nervous mechanism of the respiration by Heyman (fifty-three pages) is particularly superior

Unemployment Insurance A Summary of Some Existing Governmental and Private Plans Monograph One in a Series on Social Insurance Revised edition Paper Grátis Pp 81 New York Metropolitan Life Insurance Company 1935

This monograph brings down to date an earlier one published in 1931 The British system starting in 1911, has been frequently changed In the early years the changes generally involved extension of coverage and benefits The limited period of benefit left a large number of unemployed to be cared for by special grants Recent reorganization and the reduction of unemployment now provides for repayment of the sums advanced for such grants While unemployment insurance in Germany has existed only since 1927 it also has been revised almost

every year The latest revision and administration of the act excludes "young people in official labor camps" and "unemployed non-Aryans and "unemployed persons who have exhausted their rights to benefits" As a result "the present unemployment statistics cannot be relied on for accurate information on the situation in Germany The Danish and Swedish systems depend on national and communal subsidies to trade unions The monograph contains a survey of recent developments in the United States, including a description of Wisconsin and Ohio plans and proposed national legislation All important facts also are summarized in extensive analytic tables

Traité de physiologie normale et pathologique Publié sous la direction de C H Roger professeur honoraire de physiologie à la Faculté de médecine de Paris et Léon Binet professeur de physiologie à la Faculté de médecine de Paris Tome VII Sang et lymph Réactions d'immunité Par MM Ch Achard et autres Second édition Boards Price 120 francs Pp 181 with 9 illustrations Paris Masson & Cie 1934

The standard of this volume is maintained and improved in the present edition Particularly excellent are the chapters on blood coagulation (100 pages) by Zunz, and on immunity (118 pages) by Bordet There are good expositions of the blood hemocyanins and blood coagulation of invertebrates, on hemorrhage, on blood transfusion, and on the red bone marrow

Medicolegal

Medical Practice Acts Board of Medical Examiners May Prosecute Violators—The state board of medical examiners of New Jersey instituted this proceeding against Louis Adler, charging him with practicing medicine without a license Adler was convicted and appealed to the supreme court of New Jersey

The fact that the medical practice act specifically devolves on district attorneys the duty of prosecuting violations of the act, said the supreme court, does not thereby prohibit the board of medical examiners from prosecuting violators through any other official or attorney Adler, the court continued, had an office in which he apparently received patients He was not licensed to practice but he did diagnose physical ailments, prescribe medicines and charge therefor sums clearly indicating that it was for advice as well as for medicine This conduct concluded the court, established the fact clearly that Adler was engaged in the practice of medicine within the meaning of the medical practice act The judgment of the trial court was therefore affirmed.—*State Board of Medical Examiners of New Jersey v Adler (N J), 174 A 215*

Hospitals for the Insane Liability for Suicide of Patient—The decedent exhibited marked nervousness and his condition became so serious that a neurologist was consulted The condition was diagnosed as manic-depressive psychosis accompanied by suicidal tendencies On the advice of the physician, the decedent was placed in the Blythwood Sanatorium, the defendant in this case The decedent escaped from the institution and committed suicide The plaintiff, as administrator of the decedent's estate, sued the defendant sanatorium, and the jury returned a verdict for the plaintiff A motion to set aside the verdict was denied and the defendant appealed to the Supreme Court of Errors, Connecticut

From the evidence, said the Supreme Court of Errors, the jury was justified in concluding that the decedent was suffering from a manic depressive psychosis and that the sanatorium authorities knew, or should have known in the exercise of reasonable care, that there was an ever present danger that the decedent would commit suicide if the opportunity presented itself The defendant sanatorium contended however, that it could not be charged with negligence for the reason that the decedent was not committed to its custody by any court that there was no evidence of voluntary submission to restraint and that there being no right on the part of the sanatorium to restrain the decedent his escape and suicide did not render the defendant liable for negligence In *Mulliner v Evangelischer Diakonissenverein* 144 Minn 392, 175 N W 699 said the Supreme Court of Errors it was stated that when

a patient enters a hospital maintained for private profit, he is entitled to such reasonable attention as his safety may require, and that if he is temporarily bereft of reason and is known by the hospital authorities to be in danger of self destruction, the authorities are in duty bound to use reasonable care to prevent such an act. And with the decision of the Minnesota court in the Mulliner case, the Supreme Court of Errors of Connecticut agreed. Even if it were conceded that the sanatorium could not have legally restrained the decedent and prevented his leaving the building, it does not follow, said the court, that the sanatorium was free from negligence in failing to have an attendant with him when he left the institution. The sanatorium had assumed, for a consideration, the duty of keeping the decedent under surveillance and the suicide was the proximate result of its failure to do so. Whether the sanatorium under all the circumstances had failed to exercise reasonable care was for the jury to determine. The court concluded, therefore, that the findings of the jury were not so unreasonable as to call for interference with the verdict and that the trial court did not therefore, err in refusing to set that verdict aside.—*Hawthorne v. Blytheood, Inc. (Conn.)*, 174 A 81

Workmen's Compensation Acts Manifestation of Symptoms of Occupational Disease—The workmen's compensation act of Connecticut provides that no proceedings for compensation may be maintained unless written notice of claim shall be given within one year from the date of the accident or from the first manifestation of an occupational disease. The employee in this case, Bremner, claimed that when he consulted a physician in January 1931 for a cold and a cough, he believed that he had bronchitis and contended that he did not then actually know that he was suffering from silicosis or from any other disease due to his occupation. On April 29 1932, Bremner was forced to discontinue work, apparently because of silicosis, and filed a claim for compensation March 15, 1933. The commissioner dismissed the claim on the ground that it was not filed within one year from the date of the first manifestation of symptoms of the occupational disease, contending that such symptoms manifested themselves in January 1931. The commissioner made no ruling on Bremner's claim that he did not actually know that he was suffering from an occupational disease until within a year prior to March 15, 1933. Bremner appealed to the superior court from the commissioner's ruling but died pending the appeal. His testatrix was substituted as plaintiff and, from a decision of the superior court sustaining the ruling of the commissioner, she appealed to the Supreme Court of Errors of Connecticut.

The legislature intended, said the Supreme Court of Errors, that the duty of giving notice should arise only when a symptom of the disease should plainly appear, not when it was merely suspected. Furthermore, the duty to give notice was not conditioned by the legislature on actual knowledge but on the fact that the symptom of the disease manifested itself. An employee may not disregard that which is clear and plain, and if the circumstances are such that a reasonable man would clearly recognize the existence of a symptom of an occupational disease, it must be regarded as manifest in the sense of the statute. But, the court said, there must be a clear recognition of the symptom as being that of the occupational disease in question. However plain is the presence of the symptom itself, unless its relation to the particular disease also clearly appears, there cannot be said to be a manifestation of a symptom of that disease. The manifestation of a symptom of an occupational disease which sets running the time within which notice is to be given means its manifestation to the employee claiming compensation. The intent may not be imputed to the legislature to make the right of an employee to compensation depend on the adventitious knowledge of others, perhaps strangers to him, or the knowledge of a physician who deems it in the interest of his patient to conceal the actual facts from him, or the knowledge of a physician the interests of whose employer may well tempt him to keep silent as to the actual facts. The case was therefore remanded to the superior court with directions to sustain the appeal and to return the case to the commissioner for further proceedings.—*Bremner v. Marc Eiditz & Son Inc. (Conn.)*, 174 A 172

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Biologic Effectiveness of Alpha Particles as Function of Ion Concentration Produced in Their Paths R. E. Zirkle Philadelphia—p 558

Tumors of Blood Vessels. C. F. Geschickter, Baltimore and Louisa E. Keasbey Lancaster, Pa.—p 568

Pathologic Conditions in Prostate Induced by Estrogenic Compounds—Burrows observed that the prolonged administration of estrogenic substance to mice causes hyperplasia and metaplasia in the prostate gland. The prostates of children before birth undergo similar changes, presumably under the influence of estrogenic substance derived from the placenta. Both in mice and in new-born children, the prostatic changes thus induced are completely reversible, restitution to the normal state following a cessation of the supply of estrogenic substance. The changes found in benign enlargement of the human prostate in advanced life resemble in character and situation those observed in mice under the influence of estrogenic substance and in new-born babies. The question is discussed whether the benign enlargement of the prostate in elderly men may be due to the action of estrogenic hormones and may be a reversible condition.

Extramedullary Plasma Cell Tumors of Air Passages—Mattick and Thibadeau give a clinical and pathologic description of a case of plasma cell tumors occurring simultaneously in the nasopharynx and hypopharynx, apparently of neoplastic nature. Details of nineteen such tumors that have been previously reported and variously interpreted as granulomatous inflammatory benign or malignant by different observers are presented. The authors suggest that the occurrence of

polypoid growths in the upper air passages, of single or multiple nature, with a history of long duration, should suggest plasma cell tumor. They also suggest the use of x-rays as an aid to diagnosis. They believe that the tumors in their case are unusual and dissimilar to most of the tumors reported previously, in that they are definitely neoplastic.

Pathology of Oil Aspiration Pneumonia—Ikeda terms oil aspiration pneumonia a definite entity with a fairly characteristic clinical syndrome and constant pathologic changes. Grossly, the lung presents an appearance of bronchopneumonia. The lung is lumpy and rubbery on palpation. Yellowish mottling of the pleural surfaces may be conspicuous. The cut surface is usually dry and may show irregular areas of yellowish peribronchial consolidation usually outlined sharply against the surrounding parenchyma but sometimes merging gradually into it. Bronchopneumonic patches are usually more grayish, while small abscesses are whiter than the typical lesion of oil pneumonia. Only fluid may exude from the cut surface. Pus is expressed only in the presence of bronchopneumonia or purulent bronchitis. Nodular lesions may be encountered in chronic cases. Microscopically, the fundamental pathologic process consists of (1) massive infiltration of macrophages, (2) proliferation of stromal cells and (3) appearance of foreign body giant cells. The macrophages and giant cells usually contain droplets of oil. Globules of free oil are found deposited within distorted alveolar spaces and in the intervening pneumonic areas. In chronic cases, well localized granulomatous lesions may develop round the entrapped masses of oil. The degree of fibrosis is proportionate to the duration of the lesion.

Rapid Flocculation Method for Diagnosis of Syphilis

—The flocculation method for the diagnosis of syphilis reported by Rytz is performed as follows. The test requires only one tube for each serum. In a tube 75 mm by 10 mm, 0.15 cc of serum is placed and heated in a water bath at 60 C for three minutes. 0.05 cc of half saturated ammonium sulphate is added and mixed by shaking. The antigen emulsion, 0.05 cc., is added mixed by shaking, and 1 cc. of a 0.9 per cent solution of sodium chloride is added and rotated in such a manner that the antigen particles become evenly distributed. This is shaken in the Kahn shaker for three minutes, or by hand in such a manner that the rack, in even back and forth movements, makes about 275 movements per minute, and then 2 cc of a 0.9 per cent solution of sodium chloride is added and the tube is inverted slowly two or three times just before the reading is taken. In order not to miss a 1 plus reaction, the results are preferably read over the Fisher lamp aided by a hand lens. The slanted part of the contents of the tube should be relied on for estimating the results. A 1 plus reaction consists of tiny densely scattered flocculation particles in a slightly opalescent fluid. Plus 2, 3 and 4 reactions show clumps of flocculation in a clear fluid the clumps varying in size according to the positiveness of the serum. A negative test shows only minute antigen particles in a slightly hazy fluid without clumping. Reliable results may be obtained with spinal fluid in about eight minutes by adding 0.1 cc of half saturated ammonium sulphate to 0.5 cc. of unheated fluid, mixing this then adding 0.05 cc of antigen emulsion and mixing again. This should be shaken for five minutes, 2.5 cc of 0.9 per cent solution of sodium chloride is

added, inverted once or twice and read. The antigen employed is prepared as described by Noguchi and the antigen emulsion is prepared essentially as described by Kline except for the modifications given.

Dick Test and Blood Agar Cultures in Diagnosis of Scarlet Fever.—Gasul and Rhoads state that a persistently positive reaction to the Dick test during the whole course of the disease throws great doubt on the correctness of the diagnosis, while a positive reaction at the beginning of the disease together with a negative reaction during the course of the disease is confirmatory evidence that the disease is scarlet fever. According to their experience cultures negative for hemolytic streptococci, properly taken at the beginning of the disease on a properly prepared medium and properly interpreted, offer strong evidence against the correctness of a diagnosis of scarlet fever. A positive culture, however, in the presence of the other clinical observations of scarlet fever confirms the diagnosis.

Prophylaxis of Anemia in Infancy with Iron and Copper.—Usher and his associates compared the results of anemic infants receiving either iron or iron and copper with those of a control group receiving no medication. 1. In a series of normal children confined to an institution the hemoglobin value was found to fall sharply from the high level at birth to approximately 12.2 Gm. at the age of from 2 to 3 months, it rose slightly at the age of 5 months and then fell slowly to an average level of 11.2 Gm. at the age of 1 year. 2. A group of children receiving daily from 1½ to 3 grains (0.1 to 0.2 Gm.) of iron in the form of ferric glycerophosphate showed at the age of 1 year an average hemoglobin value 15 per cent higher than that of the controls. 3. A group of children receiving daily from 1½ to 3 grains of iron supplemented with from ¼ to ½ grain (0.001 to 0.002 Gm.) of copper sulphate showed an average hemoglobin value 19 per cent higher than that of the control group. 4. At the ages of from 8 to 10 and from 12 to 14 months, the average weight of the group receiving iron was slightly less than that of the control group, and that of the group receiving copper was from 8 to 12 ounces more. 5. The children treated with iron showed only a slight advantage over the untreated controls as to the incidence and severity of infections, while those treated with iron and copper showed a more definite advantage. 6. The children treated with iron showed a moderate advantage over the untreated controls in the mortality rate, and those treated with iron and copper a striking advantage. This advantage for the group receiving copper was especially evident in the mortality rate from pertussis. 7. In the infants who died, no relationship could be demonstrated between the ages and the amount of iron and copper per kilogram of liver or between the age and the total amount of iron present in the liver.

Alternate Suction and Pressure in Peripheral Vascular Disease.—Landis and Hitzrot exposed the extremities of twenty-nine patients suffering from advanced peripheral vascular disease to alternate suction (from -80 to -120 mm. of mercury) and pressure (from +40 to +80 mm. of mercury) for twenty-five and five seconds, respectively. These pressure variations were used for periods of from one to two hours at first once or twice daily, then three times a week and finally, as symptoms diminished once a week. Cyanosis usually diminished, symptomatic improvement was sometimes observed however, without a significant change in the color of the skin. The rest pain of ischemia was usually abolished during actual use of suction and pressure and gradually became less severe in the intervals between exposure to pressure variations. Lasting relief of pain was not observed in the presence of deeply extending gangrene or large sloughs. Ulcers, enlarging or indolent under ordinary conservative treatment, usually began to heal soon after suction and pressure therapy was instituted. Intermittent claudication became, in general, milder and exercise tolerance was slightly, but definitely, increased. Suction and pressure therapy was of no definite lasting service in patients with osteomyelitis, deeply extending gangrene or large sloughs. This form of therapy must be applied with caution, small pressure changes being used at first. The presence of acute spreading infection or encapsulated pus must be definitely ruled out before pressure variations are used. Suction and pressure therapy, if carefully applied, appear to be worthy of clinical trial in the treatment of peripheral vascular disease even when organic obstruction has advanced to the point at which arterial blood flow can no longer be increased by vasodilation. The method may be of service by increasing local blood flow temporarily during episodes of pain or ulceration so that time is gained for the development of adequate collateral blood flow.

Hypertension in Nephritis.—Page refutes Hulst's theory that the hypertension in nephritis is due to the occurrence of that the hypertensive substances in the blood, which are able to sensitize the blood vessels of animals to epinephrine. He observed that native plasma, alcoholic extracts and ultrafiltrates do not alter

the responsiveness of the vascular system to epinephrine either in pitied cats or in etherized normal cats. He finds no basis for Hülse's claim that substances which enhance the vascular action of epinephrine are present in the blood of hypertensive nephritic patients. It is possible that he mistook the increased susceptibility to epinephrine which normally accompanies its repeated administration for an effect due to plasma. Hülse and Strauss's chemical evidence as to the existence of peptone in the blood of hypertensive nephritic patients has not received confirmation by other investigators.

Etiology of Alcoholic Polyneuritis.—Strauss selected for study ten patients suffering from "alcoholic" polyneuritis and allowed them to continue their customary daily intake of spirituous liquor on condition that they consume a well balanced, high vitamin diet supplemented with yeast or its products. They were further given vitamin B concentrates and liver extract by parenteral injection in order to obviate any possible disturbance in absorption present or resulting from their use of alcohol. Improvement in the polyneuritis occurred in every instance. It is apparent that ingestion of alcohol had no demonstrable neurotoxic effect on peripheral nerves when given in amounts up to a quart a day, in patients who were partaking of an adequate diet and receiving injections of liver extract and vitamin B concentrates. Nevertheless it remains theoretically possible that even smaller quantities of alcohol so administered as to raise the blood alcohol to a high concentration might cause damage to the peripheral nerves. Investigations indicate that alcohol is poisonous to nerve cells unless there is a sufficient amount of vitamin B or some other dietary factor present to act as an antidote. The author's observations do not in any way eliminate the possibility that some impurity which might have been present in the alcohol consumed by his patients before the onset of polyneuritis was responsible for the nerve lesions. However, the data presented clearly indicate that the administration of pure blended whiskey in quantities varying from one pint to one quart daily in no way prevents the relief of "alcoholic" polyneuritis when the patients are adequately nourished. The clinical and pathologic aspects of the polyneuritis associated with alcoholism are essentially the same as those of the polyneuritis of beriberi. The high incidence of gastric secretory defects in these patients suggests that poor assimilation of nutriment from the gastro-intestinal tract plays a part in conditioning the deficiency state.

Clinical Study of Intestinal Fungi.—A study of cultures of fungi from fifty cases with various often multiple diagnoses leads Reed and Johnstone to feel that in no case did the fungus have a pathognomonic relationship to the diagnoses involved. It is possible but difficult of proof that the fungus in any case modified or influenced the symptomatology. The response to therapy was characteristic and average for the diagnoses concerned. Further survey studies would be of value in elucidating the problem of pathogenicity of intestinal fungi. Such studies should use a uniform method of culture and classification. They should be made so far as possible on patients with a single type of disease of localized residential history with repeated cultures, associated cultures of the mouth and of gastric and duodenal contents and close correlative study of the

chemical and bacterial features of the specimens of which cultures are taken.

Plasmodium Ovale Considered Modification of Plasmodium Vivax.—Both in cases of chronic infections with Plasmodium vivax and in interhuman passage of the same strain with infected blood, Giovannola observed the following modifications: ameboid movement reduced; schizonts globular, compact and of small size, premature tendency to nuclear division, small number of merozoites, and scarcity of gametocytes. Plasmodium vivax as he observed it in chronic infections and in interhuman passages is practically indistinguishable from the usual description of Plasmodium ovale. He does not believe that the modifications of Plasmodium vivax studied in cases of dementia paralytica are due to the debilitated condition of the patients, because he did not find those modifications in the strains passed through paralytic patients by means of mosquitoes even for a long time. He considers these modifications due to the long residence in the vertebrate host to whom the parasite has adapted itself by modifying its habits. The transmission of Plasmodium ovale by mosquitoes and the permanence of its morphology is an interesting experiment, but this passage was effected only for one mosquito cycle. In interhuman direct passages more than one passage is necessary to observe marked modifications of the morphology of the parasite, and further investigations on the morphology of Plasmodium ovale after more than one passage will be of great interest. Oval erythrocytes cannot be accepted as a characteristic, because these often occur in the strains passed directly from man to man. The characteristic cross disposition of pigment in the oocyst is not constant. These observations favor the view that Plasmodium ovale is a modification of Plasmodium vivax in chronic infections.

Diagnosis of Cardiac Aneurysm.—Sigler and Schneider present two cases of left ventricular aneurysm. These cases, together with some reported in the literature, lead them to the following conclusions: 1. Most cardiac aneurysms are left ventricular predominantly in the apical region and usually follow acute coronary occlusion. 2. The subjective symptoms of cardiac aneurysm are not specific being merely those of

cardiac failure or of the angrinal syndrome which may accompany similar cases without aneurysm. 3 The clinical criteria for the diagnosis of ventricular aneurysm are a history of coronary occlusion and an abnormal area of cardiac dullness over which is heard a very weak first sound, associated with a gallop rhythm usually situated near the left sternal border. 4 The roentgenographic criteria include a bulging shadow following the displacements of the heart with changes in respiration and position, and slackening of the movements of the heart or asynchronous pulsation with systolic expansion in that area. If filled with organized clot an increased area of density will be seen, and calcification if present, is suggestive. 5 The electrocardiogram is of no specific diagnostic value. Apical aneurysms, however, seem to be associated with major QRS deflections which are directed downward in the second and third leads and in the first lead with a low voltage, upward. This may perhaps be significant as corroborative evidence. 6 Although only about 0.5 per cent of ventricular aneurysms have heretofore been diagnosed during life the authors believe that, if the condition is borne in mind and attention paid to the criteria, the diagnosis will be made with increasing frequency.

Multiple Myeloma—Goord observed that profound auto-hemagglutination of the red cells occurred in dry and wet films in four cases of multiple myeloma and encountered difficulty in counting erythrocytes because of granule formation in the red counting pipet in two cases. Marked hyperproteinemia was present in three cases and was apparently present in the fourth and seemed to be the cause of these abnormal phenomena. Renal insufficiency apparently resulted from plugging of the glomerular capillaries by inspissated protein and possibly by the clumping of erythrocytes or changes in osmotic pressure due to the increased protein. Intravascular clumping was demonstrated during life by the ophthalmoscopic examination of the retinal veins in one case when pressure sufficient to slow down the circulation was applied externally on the eyeball. Prolonged uncontrollable bleeding and clotting time and increased calcium content of the serum with little change in the platelet count occurred in two cases. The observation of marked rouleau formation in the smears of two of the cases led to procedures finally making the diagnosis of multiple myeloma. Multiple myeloma with resultant renal abnormalities should be suspected in cases of atypical nephritis.

Intraperitoneal Vaccination in Surgery of Colon—Potter and Collier gave intraperitoneal injections of the bacterial antigen prepared from heat-killed colon bacilli consisting of 200,000,000 heat-killed *Bacillus coli* per cubic centimeter suspended in 1 per cent of gum tragacanth in physiologic solution of sodium chloride prepared in ampules of 30 cc obtained from Steinberg to seventy-nine patients, most of whom required major operations on the colon. A favorable clinical response and striking peritoneal reaction (seen at operation) was observed in practically all cases. This ranged from mild hyperemia of

the peritoneum to the production of an abundant exudate, in some instances giving the appearance of a true fibrinopurulent peritonitis. Peritoneal vaccination is of questionable value in protecting the peritoneum against gross fecal contamination. Its usefulness has been demonstrated as an aid to the peritoneum in its defense against minor degrees of soiling and infection. The low incidence of peritonitis (one case in the group) appears to justify the procedure as a valuable adjunct in the preparation of patients for operations on the colon. Preparation of the peritoneum by vaccination probably has its greatest usefulness in preventing peritonitis due to slight contamination, such as occurs through a microscopic perforation of the intestine at a tumor site or through the trauma to a dilated and weakened portion of intestine incidental to its surgical removal. It is in these instances that a previous peritoneal reaction with hyperleukocytosis is of real value to the peritoneum in its defense against infection.

Choledochus Cyst with Double Common Bile Duct—Swartley and Weeder present a case of choledochus cyst with double common bile duct and are of the opinion that it may occur more often and that a thorough search has not been made in those cases of choledochus cyst for a second common duct. An obstruction to the duct would seem to play an important part in the etiology of choledochus cyst, and a second duct if it is present will in all probability be sufficiently large and of sufficient diameter to drain adequately the bile into the duodenum. In their case, during the two months that bile drained from the wound intermittently, the authors were tempted to question the adequate patency or even the presence of a second duct which they had believed existed at the time of operation. The profuse drainage of bile depleted the child so that at one time they contemplated collecting the bile and introducing it through a nasal catheter into the stomach. A rhinopharyngitis prevented this. A subsequent middle ear disease and mastoiditis probably resulted from the lowered resistance due to the loss of bile. The drainage of bile through the abdominal wound ceased after two months and has not recurred. It is therefore obvious that there is a patulous common duct remaining. The hypertrophy of the left lobe of the liver verifies the fact that there was a separate duct for the right and left sides of the liver and, as the duct draining the right side was ligated, the right lobe of the liver has atrophied and the left lobe draining through the remaining duct has undergone a compensatory hypertrophy.

Experimental Studies in Alcoholism—Fleming and Stotz studied the distribution of orally ingested alcohol in the blood and cerebrospinal fluid of fifty-two subjects in order to determine whether differences occur that can be correlated with the differences in the clinical picture or in drinking habits. The volume of alcohol ingested was 0.6 cc. of absolute alcohol in a 20 per cent solution per kilogram of body weight. The chemi-

cal method for the determination of the alcohol was based on Nicloux's principle. The method was modified for use with the Folin blood filtrate. The experimental subjects consisted of eight patients suffering from schizophrenia, eight having delirium tremens, nine manifesting alcoholic hallucinosis, nine having syphilis of the central nervous system, two cerebral arteriosclerotic patients and a manic-depressive psychotic (depressed) patient, fifteen of the cases were without psychosis. According to drinking habits the subjects were divided into three groups: twenty-five heavy drinkers, fifteen moderate drinkers and twelve abstainers. Comparison of composite graphs showed that in heavy drinkers the alcohol of the blood rises more rapidly, reaches a higher maximum and falls more quickly than in abstainers, the values for moderate drinkers occupy an intermediate position. In the cerebrospinal fluid the alcohol rises more rapidly to a higher peak and falls more quickly in the heavy drinkers than in the moderate drinkers, while the curves for the abstainers occupy an intermediate position. No correlation could be demonstrated between the clinical picture and type of curve. The composite curves for the alcoholic psychoses resembled those for the heavy drinkers, and those for the schizophrenic group approached the form in the group of abstainers. The general drinking habits of each group seem to determine the shape of the composite curves.

Cerebrospinal Fluid in Tuberculous Meningitis—Merritt and Fremont-Smith point out that the cerebrospinal fluid in tuberculous meningitis has a characteristic syndrome that rarely occurs in any other disease. The determination of the cerebrospinal fluid pressure, cytology, protein, sugar, colloidal gold reaction and Wassermann reaction is necessary to establish the syndrome. Their observations were made on 297 fluids from eighty-four cases of tuberculous meningitis verified by necropsy, inoculation of guinea-pigs or the finding of tubercle bacilli in the clot or centrifuged sediment of the cerebrospinal fluid. In many cases, lumbar puncture was performed on several occasions. They found that the cerebrospinal fluid in tuberculous meningitis has the following characteristics: 1 The pressure is elevated (more than 200 mm of cerebrospinal fluid). 2 The appearance is clear or like ground glass, colorless or faintly xanthochromic, and the fluid usually shows a delicate weblike clot. 3 There is an increase in white cells (from 25 to 500 per cubic millimeter); lymphocytes predominate. 4 There is an increase in the protein content (from 45 to 500 mg per hundred cubic centimeters). 5 The sugar level is decreased (less than 45 mg per hundred cubic centimeters). 6 The chloride content is decreased (less than 650 mg per hundred cubic centimeters). 7 The colloidal gold test shows a mild midzone reaction or no reaction. If a puncture is done early in the disease, the typical cerebrospinal fluid formula occasionally may be absent. Subsequent punctures will, however, nearly always show the typical changes. The complete formula for the cerebrospinal fluid in tuberculous meningitis is nearly pathognomonic of the disease. The authors' data show no appreciable difference in the fluids from infants, children and adults. Their data confirm the syndrome first described by Deniges and Sabrazes and provide many exceptions to former statements. No hard and fast rules can be made for any single constituent in the cerebrospinal fluid. By grouping the data obtained from the several tests outlined, it is possible, however, to establish cerebrospinal fluid syndromes of diagnostic value for various diseases.

Hypothermia in Hypothalamic Lesions—Davison and Selby describe a case in which clinically the patient presented slight polyuria and polydipsia, adiposogenital dystrophy, hypersomnia and a prolonged subnormal temperature. For at least three months the temperature ranged from less than 90 to 96.6 F, the average temperature being about 92.5 F. Pathologically, an angioma situated in the floor of the third ventricle, destroyed partially the oral ends of the supra-optic and paraventricular nuclei and the right mamillary body. The nuclei tuberculi proper were destroyed throughout their entire extent. In addition, the following hypothalamic nuclei were implicated in the destructive process: the mamillo infundibular and pallido-infundibular nuclei, the substantia grisea centralis and the intercalate and interfornicate nuclei. An attempt was made to attribute the syndrome presented to the involvement of the

hypothalamic nuclei. The slight polyuria and polydipsia were most likely produced by the partial destruction of the paraventricular and supra optic nuclei. The extreme subnormal temperature is ascribed to the extensive implication of the nuclei tuberculi proper and of the mamillary bodies.

*Local Tumor like Deposits of Amyloid in Larynx: Report of Case with Review of Literature R Kramer and M L Som New York—p. 324

Tumor-like Deposits of Amyloid in Larynx—Kramer and Som observed that idiopathic or primary local amyloid tumors occur without corresponding amyloid deposits elsewhere in the body. They are to be distinguished from (1) amyloid deposits occurring secondarily in preexisting neoplasms or areas of chronic inflammation, (2) local tumor-like accumulations of amyloid occurring in the course of generalized amyloidosis and (3) tumor-like amyloid masses in generalized amyloidosis with atypical localization. The idiopathic amyloid deposits occur most frequently in the upper air passages, the larynx being the most favored site. These tumors are usually multiple and present a nodular, waxy appearance. Biopsy and intravital staining with congo red usually establish the diagnosis. Microscopically, the picture is that of a homogeneous, structureless mass of tissue that is readily identified as amyloid with the aniline stains. These tumor-like accumulations of amyloid may be without symptoms, when symptoms are present, they depend chiefly on mechanical pressure. As recurrences are frequent, total extirpation is essential. When radical removal is not feasible, radiotherapy has been found to be of great value.

Lung Lesions Induced by Intravenous Injection of Tar—Repeated intravenous injections of a mixture of tar and liquid petrolatum given to rabbits by Simonds and Curtis resulted in the following pathologic changes in the lungs. In animals that died in two weeks or less after the first injection there were only marked hyperemia, hemorrhage, thrombosis and tar oil emboli. Several rabbits that survived the last injection for six or more months showed no results from the injections except an occasional obliterated blood vessel. The lungs of seventeen of thirty-two rabbits showed varying degrees of epithelial proliferation and chronic pathologic processes. Except in primary carcinoma of the lung the authors have never observed such an extensive neoplasm-like growth of bronchial and alveolar epithelium in the human lung as was present in the lungs of many of their rabbits. It is probable, therefore, that rabbits possess a species peculiarity whereby the bronchial and alveolar epithelium may undergo extreme grades of hyperplasia and metaplasia without becoming neoplastic. Reservedly, in none of their animals did carcinoma actually develop, but the epithelial growth in several was massive, locally invasive and atypical. The character of the nuclei was not sufficiently

determinative in any case to justify a positive diagnosis of carcinoma. In all cases the changes were of multiple origin, occurring wherever granulation tissue was formed, without acquiring a definitely malignant character.

Juvenile Dementia Paralytica—Menninger states that, although there are common observations in the juvenile and the adult form of dementia paralytica, certain features are characteristic of the juvenile form of the disease. The characteristic macroscopic changes in juvenile dementia paralytica include a generalized atrophy, often hypoplasia of the brain, a marked leptomeningitic reaction, the frequent occurrence of hydrocephalus and an extensive ependymitis granulosa. The cerebellum often shows atrophy. In rare cases there is an associated formation of gummas in the brain. Because of proliferation of neuroglia both the cerebrum and the cerebellum are usually very firm in consistency. The characteristic microscopic observations include a generalized round cell infiltration, an extensive proliferation of neuroglia and microglia, an increase in the vascularity with proliferative changes of all the elements of the vessel walls, a reduction in the number of nerve cells in the cortex and changes in the nerve fibers. The frequent appearance of binucleated Purkinje cells in the cerebellum is characteristic of this disease though not limited to it. The author cites a case in which sclerosis of the posterior columns and pyramidal tracts in the spinal cord without symptoms indicating these lesions was observed. One must recognize, however, that hyperactive reflexes can occur if sclerosis of the lateral column predominates over sclerosis of the posterior column. In a small percentage of cases spirochetes can be demonstrated in the brain, the cortex, the basal ganglia and the cerebellum.

Treatment of Arthritis by Diet and Sunlight—Langstroth bases his discussion on 100 cases of chronic arthritis. He describes the degenerative, proliferative and borderline types and states that degenerative arthritis is usually favorably affected, or completely relieved, by proper dietotherapy. In seventy-two cases treated by diet, five were not improved, thirteen were slightly improved, thirty-nine were much improved and fifteen were completely relieved. The dietary history shows that, when a diet high in protective foods is instituted, relief will be most striking in those cases in which the previous inadequacy has been greatest and particularly when the amount of bread eaten has been greatest. Bread stood out most prominently in the dietary histories as having a relation to improvement when a proper diet was instituted. Physical therapy is a helpful adjunct to dietotherapy at times. Actinotherapy has a good general tonic effect on the tissues, heat and diathermy are useful in spinal arthritis with referred pain down the arm, and massage of the back muscles is helpful occasionally in spinal arthritis. Postural exercises are particularly important in sacro iliac disease and arthritis of the spine but should be used generally after the pain has been controlled by diet. The approach to proliferative arthritis is different. The patient should be allowed what small amount of activity he is able to take. The full basic diet of protective foods or as much of it as can be taken is given at once. Heliotherapy is almost indispensable in proliferative arthritis, and artificial sunlight is a poor substitute. The patients who have done best are those

who have moved into regions where sunbathing is possible for eight months of the year. After the patient is thus established and treatment begun there is an interval of several months before improvement begins, and during this period every effort must be made to support his morale. When all signs of activity have disappeared in the joints, massage and passive and active movement are begun and continued as long as there is hope of increasing the range of motion. In the borderline types of arthritis it is best to immobilize the affected joints in some form of splint until the pain is relieved and then gradually to remove it and institute massage, passive motion and diathermy. When this sort of immobilization is added to the dietotherapy and actinotherapy, such a joint will often be restored to full function in a few weeks. While improvement has been marked in both types of arthritis under the treatment outlined, any relaxation of vigilance as to diet in the degenerative group or rest and sunlight in the proliferative group will soon bring on symptoms. The author concludes that he has succeeded in arresting the progress of the disease or in restoring painless function but he cannot say that he cured it in any sense, for the old environmental conditions will allow it to progress again.

Fracture-Dislocation of the Spine—McKenzie states that in the treatment of fractures and dislocations, restoration of the normal anatomic structure is of primary importance. This principle, however, in injuries to the spinal column has been applied only in recent years, and the reason may be attributed largely to excessive fear of causing injury to the cord by attempts at manipulation. It has been found that extensive deformities can be corrected without injuring the subdural structures. Skeletal traction is often the method of choice. High thoracic fractures are treated by hyperextension on a Whitman frame. If the patient is not paralyzed, the Whitman frame can be replaced by a cast after reduction is accomplished. Patients with low thoracic and lumbar crush fractures are allowed to walk a few hours after the application of a plaster cast that holds the spine in an extreme hyperextended position at the site of injury. If paralyzed, these patients are treated on a Whitman frame in a hyperextended position. If they recover from the paralysis, treatment may be ambulatory after the application of a cast to maintain hypertension. The author outlines the care of the skin, bladder and rectum in the paralyzed patient and gives the few indications for open operation.

Coarctation of the Aorta—Farris reports two cases of coarctation of the aorta, one verified at necropsy. The diagnosis was not difficult when the condition was considered and the pulse and blood pressure in the lower limb were examined. The absence of the appearance of a collateral circulation should not confuse the diagnosis. Any young person with elevated blood pressure should have the femoral pulse palpated and the blood pressure in the arm and leg checked. The small and definitely retarded pulse and the low blood pressure in the leg are important points in the diagnosis. The blood pressure in the leg will usually have to be taken over the popliteal artery.

as in these cases the pulse in the feet and ankles is frequently not to be felt. The prognosis in coarctation of the aorta is good until adult life, especially if the diagnosis is made and the patient limits his activity. Death usually occurs in early middle life.

Insulin in Treatment of Typhoid—Hines and Walker administered insulin in addition to the routine treatment of severe cases of typhoid that showed no improvement after forty-five to seventy-two hours of general treatment. Seriously ill patients were given 3 units of insulin three times a day before meals, and this was increased to 10 units as its value was shown. The diet was forced fluids, fruit juices, citrated milk and barley gruel. In a short time the septic symptoms began to clear up fever to abate and delirium to subside, and forced feeding by tube could be discontinued and a regimen of soft diet, which was easily taken up to a point of 4,500 calories was begun. The result was most satisfactory, since the disease following the fourth day of insulin therapy had a mild course, convalescence was uncomplicated, and the patient made a complete recovery.

Preservative for Diphtheria Toxoids—Povitzky and Eisner point out that undiluted or diluted diphtheria toxoids, when kept at icebox temperature and tested after five months did not show any difference in their antigenic or flocculating

value whether preserved with 1 10,000 merthiolate or 0.5 per cent phenol. When kept at room temperature for five months, the phenol preserved toxoid diluted 1:2, though preserving its flocculating value, shows deterioration in its antigenic value. Undiluted toxoids preserved with phenol and kept at icebox temperature for nine and eighteen and five-tenths months do not compare favorably in their antigenic value with the merthiolated toxoid diluted 1:3 and kept in the icebox more than two years. Merthiolated toxoid diluted 1:3 and kept at icebox temperature preserves its antigenic value better than the merthiolated toxoid diluted only 1:2 but kept at room temperature.

Acro-dynia—Calvin and Taylor report a case of acro-dynia in which they were able to determine the source of a toxic agent. To the three most commonly advanced theories as to the cause of acro-dynia (that the condition is an infectious one, that it is an avitaminosis and that it is due to dysfunction of the vegetative nervous system) they add a fourth that acro-dynia is the result of metallic poisoning acting on the vegetative nervous system in peculiarly susceptible persons. In their opinion the metals causing this poisoning may be arsenic and lead in combination, such as is found in the widely used insecticide arsenate of lead. Some of their reasons for the theory are that before the use of insecticides the disease was unknown.

and the results of treatment point to the fact that the disease is due to the ingestion of some toxic material. Various treatments have been advocated, ranging all the way from removal of the tonsils to special diets. In almost every instance the change in diet has been brought about by removing the patient to a hospital. That lead arsenate may be the toxic article in the diet is indicated in other reports. Apparently the length of time during which the toxic agent is ingested before a change in diet is made has a great deal to do with the ultimate outcome of the disease. Postmortem observations of the nervous system are not at all incompatible with what one would expect to find in chronic lead poisoning. The authors feel that this symptom complex may well be due to the action of arsenic and lead in combination. In the case presented they know that they were dealing with arsenic and lead poisoning as well, but the clinical picture was that of acrodynia.

Cardiac Irregularities Produced by Ephedrine After Digitalis—SeEVERS and Meek recorded the effect of ephedrine on cardiac rhythm by the electrocardiograph after the intravenous injection of the drug into digitalized dogs. Doses of the two drugs were of a magnitude to allow of clinical comparison. Amounts of digitalis preparations that did not in themselves alter cardiac rhythm greatly prolonged the duration of arrhythmias produced by ephedrine. In some cases arrhythmias were brought out by the combined poisoning that had not occurred with either drug used singly. Digitalization tended to increase the number of ephedrine irregularities of ventricular type. Weakness and prostration were commonly observed during the combined poisoning. Although the arrhythmias were of a serious nature, no deaths occurred.

Study of Reticulo-Endothelial System in Trypanosomiasis—According to Pfeiffer and Tatum, if trypanosomes are treated *in vivo* for five minutes with 5 mg of arsenoxide per kilogram of body weight and the rat's blood is then placed in a test tube, the trypanosomes do not die or disappear in fifteen minutes as they do *in vivo* but continue to live on for eighty minutes. The same is true if the rat is killed five minutes after treatment, when the trypanosomes instead of disappearing from the dead host in fifteen minutes may be found and are still infective for an average of seventy-five minutes. Transplants of the organs of a treated rat taken at the time of disappearance of the trypanosomes from the blood stream indicate a greater accumulation of trypanosomes in the liver than in any other organ. Acute experiments in which the liver, spleen and kidneys are ligated support the foregoing data in that the ligation of the liver is the only procedure which materially lengthens the time of disappearance. The undoubted part played by the spleen under other experimental conditions appears to

be eclipsed by the activity of the liver under the conditions described. Since the drug has no effect on "arsenic resistant" trypanosomes *in vivo*, the logical conclusion is that arsenoxide intoxicates the normal trypanosomes, which are then removed from the circulating blood and subsequently destroyed through the activity of the reticulo endothelial system.

Occult Carcinoma of the Prostate—In 292 consecutive necropsies on men aged 50 or more, who died from a variety of causes, Rich states that frank carcinoma of the prostate was found in the routine microscopic section in forty-one. There is little doubt that a thorough search throughout each gland would have brought to light an even greater number of these tumors, many of which were so small that they were not seen macroscopically at the time of necropsy. The number discovered, however, indicates plainly that cancer of the prostate is considerably more frequent than is ordinarily supposed. In 65.8 per cent of the forty-one cases the tumor was not recognized clinically, having been in most cases of a size too small to have produced symptoms or to have attracted attention on physical examination. The tumors were most often found near the outer margins of the gland and, even when only a few millimeters in size, showed a tendency to invade the capsule.

Carcinoma of Prostate with Metastases—Graves and Miltzer made a study of eighty-one cases of carcinoma of the prostate with metastases. In all but six cases, metastases to the bone were found either by roentgen examination or at necropsy. The pelvis and sacrum were involved in 85 and the lumbar spine in 59 per cent of the cases. Pathologic fractures were observed in five instances. Treatment of the local disease was limited necessarily to measures of palliation. The plan of therapy in carcinoma of the prostate with metastases cannot be standardized, and the procedure adopted in each case will vary with the needs of the individual patient. Transurethral resection sometimes will avoid the need for more extensive surgery. High voltage x-rays and radium proved to be the most effective agents for the relief of pain due to metastases. Postmortem examinations were made in 74 per cent of the patients who died in the hospital. Metastases other than in bone were found most often in the lymph nodes, lungs and liver. Pyelonephritis was the direct cause or the most important contributing cause of death in 41 per cent. Clinically advanced renal infection may exist without significant pain and tenderness in the region of the kidney. Extensive pyelonephritis may be present without marked elevation of blood nitrogen, and the test of renal function with phenolsulphonphthalein frequently affords a more accurate picture of the degree of kidney damage than do blood chemistry determinations.

Electrical Charges on Streptococci in Genito-Urinary Tract—The technic of Heckel and his associates for studying the problem of dissociating streptococci in infections involves the determination of electrical surface charges on the bacteria, the determination of specific antibodies in the patient's serum by means of cataphoresis and the application of the newer knowledge of bacteriology causing the infection. They examined twenty cases of prostatovesiculitis to see if they could correlate the results obtained from the cataphoresis technic and the clinical symptoms presented by the cases together with a relationship between the specificity, infectivity and virulence of

the infection and the disease process. Practically all these cases showed symptoms of arthritis or neuritis or a combination of the two. All other foci of infection, such as teeth and tonsils, had been removed and sinuses drained, without any improvement in their systemic symptoms. In the majority of the cases the attention was not directed to the prostate until late in the course of the disease. In every case that presented symptoms of arthritis or neuritis the prostate was infected. In a majority of these cases streptococci were found, and the electrical charges on the streptococci showed direct correlation with the specificity of the infection. Of the twenty patients, eleven were treated with heat killed vaccines prepared from the streptococci isolated from the prostate. Four of the patients were completely cured of their systemic symptoms, six were greatly improved and one showed no improvement. With their technique the authors have been able to isolate and determine the infecting microbes, usually streptococci, in a given case of "nonspecific" infection of the genito urinary tract. Certain oxidizing types of streptococci encountered in the study have shown a virulent and nonvirulent phase that could be correlated with morphologic and biophysical characteristics.

Treatment of Severe Constipation.—Flothow reports ten cases of severe constipation in which the left lumbar sympathetic ganglionated chain, including the first four lumbar ganglions, has been removed. A comparatively normal intestinal habit has been established in eight cases. One of the failures was due to an extreme degree of asthenia, the other to organic pathologic disorders. The sympathetic innervation of the internal sphincter and the lower part of the colon travels by way of the lumbar ganglionated chain and the superior hypogastric plexus. The operation consists in interruption of the sympathetic fibers which cause spasticity of the internal sphincter and inhibit the propulsive action of the parasympathetic nerves. Cases are selected only from that class of subjects in whom constipation is a menace to health and in whom thorough medical measures have failed. The surgeon has the choice of two approaches: removal of the superior hypogastric plexus or of the left lumbar sympathetic chain. The author performs the latter operation because of its simplicity and safety.

Weil-Felix Reaction in Rocky Mountain Spotted Fever.—Davis shows that agglutinins of *Proteus* OX₁₉, as well as for OX₁₂, appear in significant titer in the serum of rabbits following injection with the passage viruses of Rocky Mountain spotted fever or São Paulo typhus. Although these agglutinins are perhaps of the group type, they cannot be so considered according to Felix's criteria. Following similar injections with passage virus of boutonneuse fever, Weil-Felix tests with the available *Proteus* X strains are essentially negative. The Weil-Felix reaction with rabbit serums confirms former observations as to the relationships of spotted fever, São Paulo typhus and boutonneuse fever. The presence of agglutinins of X₂ type in human and rabbit spotted fever serums and their absence in human and rabbit endemic typhus (United States) serums suggest that the Weil-Felix reaction may aid in the differential diagnosis, especially in regions where both diseases are endemic.

Roentgen Treatment of Laryngeal Carcinoma.—Hirsch and Baum state that 1. In intrinsic cases clinical cures can be obtained by roentgen treatment in cordal, glottic or subglottic, noninfiltrating, keratinizing, fully differentiated squamous cell epitheliomas. In such cases surgery gives equally good results, but with a lesser degree of conservation of func-

tion and with an average operative mortality of about 15 per cent. 2 In extrinsic cases in which the tumor involves the epiglottis, glosso-epiglottic folds, valleculae, pyriform sinus hypopharyngeal and lateral pharyngeal and postericoid regions the prognosis is usually unfavorable, owing to the tendency to rapid spread and metastatic glandular involvement. In this group, surgery gives a high mortality and offers no assurance of cure. Roentgen therapy can produce a clinical cure in this group with cervical involvement, or, if the case is hopelessly advanced, palliation, comfort and prolongation of life.

Intratracheal Use of Iodized Oil in Asthma—Brilyent and his associates believe that an ideal medium for the treatment of the mechanical factor in intractable asthma is an iodized oil that is nonirritating, nonabsorbable, of moderate viscosity, of a sufficient gravity (from 1.225 to 1.4) so the oil is not easily coughed up and of an iodine content sufficiently high to make it a good contrast medium for bronchographic purposes. The intratracheal method of administering the oil is the procedure of choice for diagnostic and therapeutic purposes. Usually only the lower section of the bronchial tree need be injected when the oil is used as a therapeutic measure in asthma. The filling of the left lower section is somewhat difficult, the correct position of the patient is important. For bronchograms, from 15 to 20 cc of iodized oil should be put on each side. For therapeutic purposes, from 5 to 10 cc should be given at weekly, biweekly or monthly intervals. Of the fifty cases of intractable asthma in which the authors obtained poor results by allergic management, they obtained good results in 70 per cent by combining the use of iodized oil intratracheally with allergic management. The therapeutic value of iodized oil given intratracheally to the intractable asthmatic patient appears to be due primarily to the mechanical effect of the oil. The intratracheal use of iodized oil cannot in itself cure a patient suffering from allergic asthma, but it is of inestimable value as a means of forcing up bronchial plugs and replacing pockets of pus with a nonirritating, nontoxic substance. In the treatment of intractable asthma, eliminative measures and desensitization against the substances to which the patient is specifically sensitive are of first importance, and the intratracheal use of iodized oil in the bronchial tubes is next in importance. A combination of the specific and the mechanical is ideal treatment in cases of intractable asthma. The authors feel that iodized oil is an indispensable measure in the treatment of cases of intractable asthma.

Precancerous and Carcinoid Lesions of Cervix Uteri—Henriksen is of the opinion that the microscopic diagnosis of cervical cancer will not be improved until both the clinician and the pathologist learn more about pseudomalignant and possible promalignant lesions of the cervix. Mitotic figures are occasionally seen in the basal layer of the normal cervical epithelium and are to be looked on as evidence of the normal growth and repair of the cervix. Cervical lesions may be spoken of as "precancerous" when it is understood that the term implies that they might, though not necessarily, become cancerous. The microscopic picture of these lesions is less perplexing if the mechanism of development is understood. That cancer does originate in the so called metaplasias is illustrated by one case. Leukoplakia of the cervix is a pathological entity that may show cellular changes suggestive of cancer, though invasion is always lacking. Two cases showing microscopic changes similar to both Bowen's disease and extramammary Paget's disease are described, and also a case of intracervical carcinoma diagnosed with the aid of the Schiller test, in which the malignant growth extended over the entire endometrial surface of the uterus. The importance of biopsy is indisputable, but its value is increased if the specimen is immediately fixed and serial sections are made. Serial sections are of especial importance in cases of suspected early cancer.

The application of compound solution of iodine with the atomizer simplifies the test. The Schiller test is undoubtedly of some value in the diagnosis of early cancer, whether it is a specific for the absence of the cancer is questionable.

Transperitoneal Nephrectomy for Malignant Tumors of Kidney—Wharton believes that transperitoneal nephrectomy is safer than lumbar nephrectomy for the removal of renal tumors. He presents the following technic. A long rectus incision is used. Since the size of renal tumors can be reduced by preoperative irradiation, it is unnecessary to make a right angle extension of this incision into the flank. Exposure is improved by hyperextending the back as in an operation on the gallbladder. The anesthesia must be fairly deep. The operator works directly across the peritoneal cavity. The hyperextension of the back brings the lumbar wall nearer to the surface and the big incision makes it entirely unnecessary to work in a hole. The intestine is pushed into the opposite half of the abdomen and the layer of posterior peritoneum is incised at least 2.5 cm. from the lateral margin of the large intestine and mobilized before it is cut well above the flexure of the large intestine, which is then pushed medially and held back by gauze and retractors. The peritoneum is also pushed away from the region of the renal pedicle and the kidney. The duodenum goes with the peritoneum and ascending colon. If the kidney tumor and the peritoneum are intimately adherent, a wide patch of peritoneum may be left on the kidney and removed with the tumor. The elevation of the posterior peritoneum uncovers the retroperitoneal mass. The renal pedicle and pelvis are hidden under a layer of loose fat. In ligating the renal pedicle, it may often be advantageous to mobilize the lower pole of the kidney. It is always necessary to push the peritoneum and all other structures away from the region of the renal pedicle before attempting to isolate it. Before the renal artery and veins are clamped and controlled, it is always wise to expose them thoroughly and remove the fat and areolar tissue by which they are concealed. They should be elevated from the bed in which they lie so that a ligature may be passed around them. It is essential that there should be no back bleeding from the tumor or kidney at any time, as this blood will probably contain cells of the tumor. After the blood vessels have been ligated and cut, the removal of the tumor is usually fairly simple. All the perirenal tissue possible should be removed, including the perirenal fat, Gerota's capsule (the perirenal fascia), a long strip of the ureter and all the areolar tissue that can be removed safely. The posterior layer of peritoneum is closed tight by a continuous suture of plain catgut. If drainage is necessary, it can be provided through a stab wound, extraperitoneally, in the flank.

Branchial Carcinoma.—Crile and Kearns discuss twenty-eight cases of branchial carcinoma, all of which were definitely diagnosed. The only available methods of treatment are irradiation with radium or the x-rays and radical removal. Roentgen treatment is purely palliative. The method of treatment that they employed in most of their cases has been a combination of surgery and x-rays. Nitrous oxide anesthesia should be employed. Of the twenty-eight patients, eleven were treated by surgery alone. Two died from postoperative bronchopneumonia. Five left the hospital, four in good condition on discharge, but the fifth patient was unable to swallow owing to paralysis of the glossopharyngeal nerve. Two of the four remaining patients died, nine and ten months after operation. Six patients were treated by surgery and postoperative high voltage roentgen radiation. One died following a laryngectomy, which was performed because of the extension of the tumor into the pyriform sinus. Two others died one at the end of three months after operation after only one course of roentgen irradiation, the other at the end of eleven months after operation following three courses of irradiation over the entire side of the neck and head. One patient, who was treated with one course of radiation preceding operation, and postoperative radiation with x-rays and 2,080 mg. hours of radium, died twelve months after operation. Of five patients treated only with roentgen radiation distributed over the head and neck, two died within three months and one lived seven months. One patient was treated with radium alone, receiving 2,340 mg. hours at the first treatment and 2,600 mg. hours two months later and died six months after the first treatment. The four

patients treated with both roentgen and radium radiation died within a period of nine months after the first treatment. Only palliative results can be expected from any treatment, as the disease is usually rapidly fatal. It seems probable that radical excision followed by irradiation offers the best chance of relief to the patient having a branchiogenic carcinoma.

Pituitary Basophilism—Teachenor submits the clinical and postmortem observations of a case of pituitary basophilism in which fatal erysipelas intervened so promptly after the recognition of the basophilism as to preclude further examinations. The unusual feature of the case is the infiltration of the adrenals, the kidneys and bone with cells which are identical with those of the pituitary neoplasm. The presence of these neoplastic cells in the kidneys and bone tends to disprove that basophil adenoma stimulates the growth of basophil cells in other organs of the endocrine system. Other features of the case are the high basal metabolic rate without loss of body weight and without evidence of thyroid hyperactivity and the marked uterine hyperplasia in the presence of marked involutional changes in the ovaries. It is not clear why an adenoma of the basophil cell, which is thought to secrete a gonad stimulating or sex maturing hormone, produces a precocity of sexual characteristics in children and eventually underactivity of sex function rather than stimulation.

Encephalomyelitis Simulating Diphtheritic Paralysis—Wyard and Hobhouse present four cases of encephalomyelitis that suggested diphtheritic paralysis and believe that a new significance should be attached to some of the most typical symptoms of diphtheritic paralysis. The feature common to all four cases was absence of deep reflexes in the legs, without gross paralysis or muscular wasting—a breach of the reflex arc which was probably mainly on the afferent side. Palatal paralysis was observed in three, and three gave a history of disorders of the throat. In one case the only history of sore throat was immediately preceding the onset of the paralysis. In one case there had been a history of diphtheria in the same house after the onset of the child's symptoms. Three cases were clinically compatible with diphtheritic neuritis, though none of them showed a defect of ocular movements. The other case combined the usual signs of diphtheritic neuritis with others which were incompatible with it—that is, multiple lesions of the upper motor neuron, which were slight and transitory. With the exception of one child who died of bronchopneumonia, all made good progress while in the hospital, and their physical signs cleared up partially or completely. The last case bore a strong clinical resemblance to many cases of mild spontaneous encephalomyelitis observed recently, except in that heretofore palatal paralysis has not been observed in this disorder. The few postmortem changes observed in the fatal case were quite compatible with it and to some extent suggestive of it. The authors believe that most probably all four patients suffered from this condition and they suggest that further experience may show that palatal paralysis is a symptom of a type of encephalomyelitis prevalent at the moment. None of the children were seen in an early stage of illness when confirmatory evidence might have been obtained from a cellular reaction in the cerebrospinal fluid.

Gastric Acidity of Monkeys—Ferguson and Smith found that acetyl-beta methylcholine, in sufficient dosage, e. g., 3.5 mg per kilogram of body weight by lateral cerebral ventricle, 7 mg intravenously, and 10 mg subcutaneously, temporarily abolished the free acidity in the test meal gastric contents of the green monkey. The total chlorides were not affected. As with pilocarpine, but much less strikingly, the intraventricular route had the lowest threshold. Vagotomy in one case slightly raised the intraventricular threshold, but to a degree that can hardly be considered significant. Atropine antagonized the anacidity effect of acetyl-beta-methylcholine chloride as with the other parasymphathomimetic drug, pilocarpine. There was even less evidence than with pilocarpine that simple neutralization played any significant part in the production of the gastric anacidity. Preliminary experiments with posterior pituitary extracts have failed to demonstrate any anacidity response to the intraventricular injections tried.

Epinephrine Content of Adrenals in Scurvy—Deutsch and Schlapp observed that there is an absolute reduction in the epinephrine content of the adrenals of guinea pigs in scurvy. There is a reduction in the epinephrine content of the adrenals of guinea-pigs in inanition, and this must be an important factor in the reduction found in scorbutic animals. There is no significant change in the cevitamic acid content of the adrenals in inanition when sufficient green food is given in the diet. There does not appear to be any close physiologic relationship between cevitamic acid and epinephrine.

Rapid Diagnosis of Cerebrospinal Fever B G Macgrath—p 543

Chorea and Psychosis—Lewis and Minski discuss three cases of chorea with psychosis in young adults and one of dubious choreic movements in a fatal case of schizophrenia. The etiology is always assumed to be toxic, but it is recognized as possible that here, as in Sydenham's chorea of children, not only may a rheumatic infection and other environmental factors be held responsible but also a constitutional predisposition and

an intoxication of some sort responsible for provoking the present attack. In a majority of those who have chorea during adult life, a history of chorea minor during childhood can be elicited. The analysis of the clinical observations and the anatomic changes in fatal cases suggests an interference with a complicated system covering cerebellomesencephalothalamocortical connections. A system rather than a "center" or a limited anatomic site is affected. Pregnancy appears peculiarly able through endocrine or toxic influence to revive or possibly to elicit the first instance. The occasional occurrence of choreic symptoms in epidemic (lethargic) encephalitis or, in later life, in focal disease of the brain suggests that it is not only rheumatism that may affect this "system" in so special a way. The anatomic observations are not yet relevant to clinical issues. In children with the familiar St. Vitus's dance, the usual changes are lability of affect and irritability, these are seen as naughtiness, outbursts of anger or crying and resentment at sensory stimuli, in others there is lessened spontaneity, often masked by the choreic movements. In more severe cases, usually in older children, the same changes are accentuated, and in the fleeting phases of anger or terror there may be slight delusional trends. Still more severe forms with delirium, hallucinations, delusions of persecution and much excitement are seen in adults. The relation of psychic changes to the other features of the disorder is not easy. At first one would assume that they belong to the symptomatic psychoses and exhibit the familiar features of an acute and more or less severe exogenous disorder. But it is unwise to ignore the presumptive localized changes in the connections between cortex, cerebellum and basal ganglions.

*Standardized Tuberculin (Purified Protein Derivative) for Uniformity in Diagnosis and Epidemiology. E R. Long, Florence B Seibert and J D Aronson—p 304

Standardized Tuberculin—Long and his co-workers point out that the active principle of old tuberculin can be isolated by a method that they outline and put up in dry form such that the essential requirements of a standard, viz., specificity, high potency, constancy in strength and stability, are ensured. The active principle as it exists in old tuberculin is a protein derivative. In its present refined form it has been designated purified protein derivative from tuberculin. Optimal dosages of this substance for epidemiologic work and testing of child and adult tuberculous patients have been established on the basis of several thousand tests. The doses selected are 0.00002 mg by weight of the purified protein derivative for the initial test and 0.005 mg for injection of those failing to react to the first dose. Experience has shown that the small first dose detects all the highly sensitive cases, without danger of excessively severe reactions, while the second dose detects the remainder of positive cases, that is, those whose sensitiveness is such that they would respond to the conventional doses of

preparations of tuberculin of strength equal or superior to that of the international standard. Several series of tests in the United States, England and Wales are reported, in some of which comparison with old tuberculin and roentgen observations is recorded. The roentgen examinations indicate that the purified protein derivative, like other tuberculins, may fail to detect an occasional case of healed primary tuberculosis with calcified foci, but that cases of clinical significance are not missed. The incidence of positive tuberculin reactions to the purified protein derivative in surveys in England and Wales varied from 38 per cent in children, 16 years of age or less in an orphan asylum, to 100 per cent in a tuberculosis sanatorium for adults. Almost all adult patients with tuberculosis reacted to the first dose. In the United States during the fall of 1934 the purified protein derivative was used in testing about 8,000 college students in various parts of the country. In the east about 50 per cent of the students reacted positively, in the middle west from 25 to 30 per cent and on the west coast about 50 per cent.

Tuberculous Disturbances Under Mask of Rheumatic Conditions—Tan states that the assertion of Loewenstein and his co-workers that tuberculous bacillema is responsible for rheumatic arthritis and other rheumatic manifestations cannot be accepted at present and needs further confirmation. Whether rheumatic conditions are the result of releasing the responsible nova sensitized by tubercle bacilli or whether they are variants of tuberculous infection in a soil of altered immunity is a field for further study. Arthritis or polyarthritis caused by tubercle bacilli may be in the form of Poncet's rheumatism or of the usual chronic tuberculous arthritis. In muscular pain of the chest, pulmonary tuberculosis should be considered in the differential diagnosis. Lumbago and sciatica are only symptoms and frequently carries of the vertebrae may be the underlying cause, though it should be differentiated from spondylosis deformans and ankylopoietic spondylarthrosis. Tuberculosis of the tonsils is not infrequent and may be accompanied by rheumatic pains of the joints and elsewhere. The tuberculous origin may be revealed months or years after the onset of rheumatic manifestations and its possibility should be kept in mind when these manifestations are preceded or accompanied by pleurisy or tuberculosis of other organs. Rheumatic conditions are merely symptoms. These may be caused by other micro-organisms, of which the tubercle bacillus is one of the most common.

Treatment of Tumors by Cobra Venom—Lavedan has treated fifty-one cases of histologically confirmed cancer by injections of cobra venom. The venom was prepared in Professor Calmette's laboratory and contained 10 mouse units per cubic centimeter. The initial dose was 0.5 cc., 1 cc., 5 mouse units. Three injections were given at two day intervals. The dose was regularly increased by 5 units every three injections until 50 units was given at one injection. At this dosage the injections were given twice a week or every five days. In some instances the injections were made directly in the tumor. The author concludes that the venom has no action on human cancers. A few cases of improvement were noted, but these may be explained on the basis of the occasional spontaneous stabilizations or regressions known to occur. The action on cancerous pain is undeniable, but it is inconstant, irregular, often slow, and habituation may occur. In dealing with incurable cancer, therefore, the author feels that venom may be reserved for the rare case in which morphine cannot be used.

Diencephalic Nuclei in Epilepsy—Salmon reviews the evidence concerning the epileptogenic properties of the diencephalic nuclei, which he feels is adequate in demonstrating that experimental and pathologic lesions of these nuclei are translated into convulsive phenomena. This conception accords with the vegetative and hormone properties of the tuberian nuclei and clarifies the pathogenesis of numerous cases of diencephalic epilepsy recently reported. The idea of an epileptogenic center in the infundibular region, however, does not signify that epilepsy is always due to diencephalic changes. Epilepsy of cortical origin is more frequent than that of subcortical origin. This may perhaps be explained by the suppression of cortical inhibiting action on the subcortical centers. In any case the temporary improvement of epilepsy under the influence of barbiturates favors a close diencephalic connection between this manifestation and other functions, such as sleep, temperature and sugar regulation.

Osteosclerotic Anemia (Case of Marble Bones)—Assmann reports a case of generalized osteosclerosis and anemia in a man, aged 25. The bodily structure of the patient was infantile. Roentgenoscopy disclosed that the greater density of the bones was most pronounced in the metaphyses and in the epiphyses, while the diaphyses of the long bones were only slightly involved. Histologic examination revealed that the bone marrow had become largely displaced by trabeculae or by fibrillar and infiltrated connective tissue. Between these there were a few medullary foci with signs of active erythromyelopoiesis. In the greatly enlarged lymph glands and in the enlarged spleen and liver, hyperplastic changes were evident. The histologic examination revealed in these organs active blood formation. The entire reticulo endothelial tissue was in a state of chronic

proliferation. It showed chronic inflammatory and fibrous changes but was also in a stage of regenerative, almost embryonal blood formation. The author thinks that the myeloid metaplasia in the spleen, the liver and the lymph nodes was a process of compensation for the deficient hematopoiesis of the bone marrow. The cause of the bone disease was unknown in this case whether osteomyelitic processes were involved cannot be definitely decided, but a tuberculous cause could be excluded. The maxillary suppuration, which developed shortly before death and which has been observed in other cases of marble bone disease, probably originated in the teeth and progressed because of lowered resistance. The author thinks that the infantilism, which, among other factors, was manifested by the persistence of the epiphyseal lines and the hypoplasia of the genitalia, is probably caused by a functional disturbance of the hypophysis. Necropsy revealed that the hypophysis was small and that its cortical portions were atrophied. It is probable that the thickened bony structure of the sella turcica was responsible for these hypophyseal changes. Other secretory disturbances, particularly those of the parathyroids, were absent and there were no indications of a primary leukemic blood disease. Investigation revealed nothing that would indicate a familial occurrence.

Coin Test in Pneumoperitoneum—Pozzi studied the coin test in ten subjects with experimental pneumoperitoneum and found that, applied to the abdomen, it is always positive when there is a sufficient quantity of free air in the peritoneal cavity. By introducing 50 cc. of oxygen at one time, the author observed that after 200 cc. there is a distinct change from the dullness on auscultation to a certain degree of sonority. Changes in liver dullness are slight. Both the liver and the spleen appear to be detached from the diaphragm at the esophageal hiatus and the foramina for the passage of the large veins. In the recumbent position on laterolateral projection, with the quantity of gas introduced the detachment of the anterior aspect of the liver from the abdominal wall may be seen as a transparent band, larger than a fingerbreadth. The percussion sound becomes clearer on introduction of more oxygen, acquiring a metallic quality when from 900 to 1,000 cc. of oxygen is introduced. At this point the roentgen presentation of the pneumoperitoneum is naturally much clearer. In the erect position the dome of the diaphragm is raised notably, often to the right, where the area of transparency has a height of almost five fingerbreadths. The detachment of the diaphragm from the abdominal organs appears complete. The pneumoperitoneum appearance in the recumbent position in laterolateral exposure is notably more accentuated than that observed in the preceding position. The author believes that, when the quantity of gas in the peritoneum is much less than may be evinced by roentgenography alone, the coin test may be useful, even though the sign may not be completely positive, the changes in the resonance are such as to justify a suspicion of pneumoperitoneum. The coin test applied to the abdomen may offer an important symptomatic indication of the presence of free gas in the peritoneum. The author sought to determine whether the test is useful in detecting an extensive abdominal meteorism and in differentiating between simple meteorism and pneumoperitoneum. For this purpose he gave insufflations of air in the colon to some subjects and administered by mouth the powders of Frerich to other subjects, thus obtaining distention of the colon, of the stomach and, to some extent, of the small intestine. For the stomach the results were completely negative. The test was also negative in distention of the small intestine. In all cases of insufflation of the colon, the coin test was positive in the erect and the recumbent positions.

*Diathermy of Carotid Sinus in Hypertension M Sorrentino—p 284

Diathermy of Carotid Sinus in Hypertension—Sorrentino stimulated by means of diathermy the carotid sinus of sixteen patients, aged 50 and more, presenting various degrees of hypertension. Seven of the patients were women and nine were men. Four had vascular lesions and were hemiplegic. Ten showed signs of renal sclerosis. Frequent urinalyses and systematic determinations of the blood pressure were made and during treatment all medicaments were withheld. When a patient, after from four to five determinations of blood pressure taken in the recumbent position on different days and on the same arm, presented a constant figure, pulse and respiration diathermy was administered on alternate days. After ten minutes and while treatment continued, another determination was made without removing the armband, and a final determination after the regular fifteen minutes of treatment. Applications were occasionally extended to from twenty to twenty-five minutes. The electrodes used were 10 by 15 cm in size. The intensity varied with the individual tolerance from 350 to 400 milliamperes to from 1000 to 1,100 milliamperes. Treatment was well tolerated. Arterial pressure was lowered in almost all the patients. Several felt markedly better. After ten minutes of treatment, the maximal pressure was lowered by 0.5, 1 or 1.5 cm of mercury and at the end of the treatment was 1, 1.5 or 2 cm of mercury lower. After fifteen treatments the pressure was reduced from 1 to 5 cm of mercury. The minimal pressure was lowered from 1 to 2 cm of mercury. The pulse was increased in frequency (from eight to ten beats) after each treatment. The marked lowering was observed in cases of strong hypertension while in cases of mild hypertension the change did not take place to the same extent. In the female patients the lowering effect was quicker, clearer and more marked. The duration of this lowering of pressure varied. After a month or a month and a half the pressure generally rises again especially in cases of slight hypertension. In patients with a maximal pressure exceeding 20 cm of mercury, the pressure rises six months after treatment but does not attain the original height remaining from 1 to 2 cm of mercury lower. When treatment is protracted more than from twenty-five to thirty minutes the patient has a feeling of warmth in the head and shows redness in the face but no serious symptoms. It is significant that after from one to three months many patients return for treatment saying that during and often after the period of treatment, they experienced a sense of euphoria in all their vegetative functions and that the buzzing in the head and other cephalic disturbances had disappeared.

Peritoneal Tuberculosis in Infants Case R Monteverde and I Diaz Bobillo—p 497

Disturbances of Dynamism of Uterus—Leon found that the disturbances of the uterine dynamism especially general spasmodic contractures and local contractures in certain segments of the uterus in the course of labor are frequent in women suffering with gravidic nephropathy (43 per cent in his group of 111 nephropathic pregnant women). Having in mind different degrees of intensity of gravidic toxicosis in the edemonephrotic and eclamptic syndrome he observed that dystocic labor due to disturbances of the uterine dynamism is frequent in women with attenuated forms of gravidic toxicosis (45 per cent) rare in women with grave forms (36 per cent) and nil in eclamptic women who in his group had a normal delivery. The frequent functional disturbances in gravidic nephropathy are explained by interpreting the condition as a general disease in which there are considerable changes in the blood and alterations of the sympathetic endocrine system. It

the results of further statistical studies, planned by the author prove that labor follows a rapid evolution in women who immediately after delivery or a few hours later suffer from eclamptic attacks, the rapid evolution of labor, in these cases, could be related to an overproduction of hormones of the posterior lobe of the hypophysis, which have been considered important pathogenic agents in the production of convulsions.

*Anterohypophyseal Functional Insufficiency as Cause of Habitual Abortion A C Kunz—p 894

Habitual Abortion—Kunz says that cryptogenic habitual abortion is due to a functional insufficiency of the anterior lobe of the hypophysis. This insufficiency produces a functional insufficiency of the corpus luteum, the placenta, the adrenals and the interstitial gland. The author succeeded in preventing abortion, after appearance of the bloody discharge, in five women suffering from habitual abortion, by the following treatment. The patient is kept in bed as long as the bloody discharge persists. At the same time she is given two daily injections of 1 Gm each of a preparation of extract of corpus luteum. Although the discharge regularly stops in two or three days, the treatment is continued for three days more. By this time the patient may leave the bed. The total quantity of extract of corpus luteum given to the patient during the treatment varies between 6 and 10 Gm. Immediately after discontinuation of the treatment, the patient is given 200 rat units of anterior pituitary-like principle daily until she has passed the fourth month of pregnancy. In the author's cases the time varied between forty and sixty days and the amount given each patient was about 12,000 rat units. The five patients who received the treatment each delivered a normal living child at term.

Porphyrin Elimination in Hyperemesis of Pregnancy—Herold determined by means of the spectrophotometric method, the porphyrin content of the urine of twenty-one women with hyperemesis of pregnancy. He found that in fifteen the porphyrin elimination was increased in comparison to that of normal pregnancies. After an increased disintegration of erythrocytes had been excluded as the cause of the increase in the porphyrin content, an impairment of the hepatic function was considered the cause. This etiology was further corroborated by the outcome of the simultaneously conducted liver tests (galactose test, xanthoprotein test, determination of the bilirubin content of the serum and determination of the urea). Repeated tests on the porphyrin content in the course of the disturbance disclosed that an exacerbation of the condition was generally accompanied by an increase in the porphyrin elimination and an improvement by reduction in the elimination.

Reduction Substances in Blood of Eclamptic Patients—Dietel stresses the significance of glutathione in the metabolism of the organism. In studies on patients with preeclampsia and with eclampsia he found that the glutathione values are reduced proportionately to the severity of the eclampsia. Studies with different analytic methods revealed the lack of substances that have been designated as x-substances but have been found to be identical with cevitamic acid (vitamin C). The latter is a reducing substance; it plays a part in the process and regulation of the cell oxidations. The decrease of the cevitamic acid in the blood of patients with eclampsia permits the conclusion that the oxidation and reduction processes of the cells are diminished in this disease.

Therapy of Juxtapyloric Ulcer—Henning and Norpoth point out that the juxtapyloric ulcer particularly its most frequent manifestation, the duodenal ulcer, is characterized by the nocturnal and hunger pains and by the superacidity and supersecretion. Tests have revealed that whereas in normal persons the secretion ceases some hours after the onset of sleep it continues in patients with duodenal ulcer. After calling attention to the acid factor in the pathogenesis of ulcer which, they admit, is not completely clarified as yet the authors point out that in view of the constant nocturnal secretion in patients with duodenal ulcer, nocturnal therapy is really more important than diurnal treatment. In their search for substances that would counteract the secretion of hydrochloric acid, their guiding thought was to realize this aim by osmotic impairment of the cells of the mucous membrane. They experimented with hypertonic solutions of dextrose and found that in cases of superacidity the acid secretion ceased for the duration of the dextrose action. The treatment that they evolved from this observation consists in the administration of small quantities of dextrose at short intervals. The technique is as follows. During the first days of the treatment the patient is given at hourly intervals 50 cc of a 60 per cent solution of dextrose. A thin stomach tube is introduced every evening through the nose and through it the same quantities of dextrose solution are introduced hourly during the night. Depending on the severity of the disorder, this strict form of treatment is continued for a shorter or longer period of days, but it is usually possible to add some zwieback with butter on the third or fourth day. The diet is gradually extended. The dextrose treatment is continued unchanged. Under the influence of this treatment the acidity was reduced and the symptoms disappeared promptly. There was no loss of weight, even during the days when only dextrose was given. In the later course, the weight increased as a rule. Some of the patients complained of heartburn during the first few days but aside from that there were no undesirable secondary effects. The blood sugar showed a normal behavior. The experiences with this treatment cover two years.

 Kauffmann's Water Test as Functional Test of Heart During Childhood S Syman—p 175

Functional Test of Heart During Childhood—Svntian investigated whether Kauffmann's water test is suitable for the determination of the heart action of children. His tests were made on thirty patients. Of eighteen children without heart disease sixteen gave a negative reaction. In one of the two remaining children a more thorough examination made the existence of cardiac impairment seem probable. The other child was not examined again. Five children with heart disease, who were in the stage of latent decompensation, had a positive test, while one child in the stage of manifest decompensation had a negative one. Of four children with suspected cardiac impairment, two had a positive test which corroborated the existence of a cardiac defect. In the two other children the outcome was negative. Two children with an increased lability of the circulation had a negative test. Kauffmann's assertion that in patients with heart disease, during the stage of latent decompensation, elevation of the feet increases the diuresis was thus corroborated in the author's studies on children. He was unable to corroborate the statements of several other examiners who assert that patients without heart disease react in the same manner. He concludes that Kauffmann's water test can be used as a test for the cardiac function of children. However,

he thinks that studies on a larger clinical material will be necessary in order to determine to what extent the outcome of the test can serve as a basis for therapeutic and prognostic decisions. At any rate, together with the results of other clinical examinations, Kauffmann's test is helpful in the estimation of the cardiac condition.

Influenza in Man and Distemper in Dogs—Nörr calls attention to influenza-like disorders in domestic animals, particularly horses and dogs, and points out that Bemelmans in a report published in 1932 directed attention to similarities between the influenza-like disturbances in horses and dogs and human influenza. He further discusses the possibility of a transmission of the disturbance from animals to man or vice versa. In considering this problem he gives his attention primarily to distemper in dogs. He observed that since the winter of 1933-1934 a nervous form of distemper with convulsions, paralysis and compulsion movements became more frequent among dogs and that this form reached its maximum during the winter of 1934-1935. He thinks that this severe form of distemper is the result of an increased virulence in the causal organism and although the greater incidence of this form of distemper shortly before the outbreak of the influenza epidemic does not necessarily imply a relation between the two disorders, this factor does deserve consideration. In this connection it is pointed out that human influenza as well as distemper is transferable to ferrets and that distemper also occurs in monkeys. According to Nicolle human beings are susceptible to the virus of distemper and may be virus carriers. Moreover, another French bacteriologist Remlinger suggested treating dogs that have distemper with human convalescent serum, and the author, in turn, suggests that serum from dogs that have had distemper may eventually be of therapeutic value in severe cases of human influenza the more so since serums of animal origin are used effectively in other infectious diseases.

"Caisson Disease" of Hip Joints—Frank reports a case in which a man aged 41 when employed at bridge construction, developed severe formication in the left hip joint. It appeared suddenly when one day decompression had been done somewhat too rapidly. He felt comfortable only as long as he was in the chamber. Later severe pains developed in the hip joint and the severity of the pains fluctuated. During the third year the symptoms increased considerably and he came under the author's observation. The left hip joint was sensitive to pressure and the movements were somewhat restricted. Roentgenoscopy disclosed areas of lesser density in the head of the femur. Moreover on the rim of the head there were excrescences so that the entire lateral surface had an irregular outline. The articular space was diminished. The region between the upper rim of the head of the femur and the neck of the femur appeared as if gnawed on. The right hip joint was free from these changes, but here too honeycomb like areas of lesser density appeared. The seroreactions for syphilis were positive but the roentgenologic aspects of the articular disorder did not resemble syphilitic changes. The possibility of caisson disease was taken into consideration but no definite diagnosis was made. The patient died two years later as the result of pneumonia and pulmonary embolism. The postmortem examination of the hip joint corroborated the roentgenologic aspects, but a histologic examination of the hip joint was neglected. A recent report in the literature which described the impairment of the hip joints in four caisson workers in whom the anamnesis and the roentgenologic aspects were similar to that of the author's case, convinced him that the patient observed by him must have had caisson disease of the hip joint. The bone lesions resemble greatly those that are observed in caisson disease of the skin (marmorations and aeremia), of the internal ear or of the spinal cord and the brain.

Lymphatic Angina (Monocytic Angina)—Otto describes six cases of lymphatic angina (monocytic angina). During the beginning stage the diagnosis is rather difficult particularly when examination of the blood is neglected. It may prove difficult to differentiate the condition from diphtheria beginning cervical abscess and acute lymphatic leukemia. In one of the patients observed by the author several complications developed: pneumonia, pleurisy, orchitis and hyperthyroidism. In most cases the course of the disease was similar to that of Plaut-Vincent's angina. The pharyngeal culture contained in four cases spirilla and fusiform rods, and in one case fusiform rods without spirilla. Generally the sedimentation speed of the erythrocytes was but slightly accelerated somewhat as in Plaut-Vincent's angina. The question whether the lymphatic angina is the anginal form of Pfeiffer's glandular fever has not been completely clarified. The examination of the blood, which discloses an increase in the lymphocytes and the appearance of numerous cells resembling lymphocytes is extremely important for a prompt diagnosis. A deviation to the left resulted in the case in which a complicating pneumonia developed so that the increase in the lymphatic cells was no longer so noticeable. The author points out that an agglutination reaction may eventually prove helpful in the diagnosis.

Observations in Epidemics of Meat Poisoning I. Hammerschmidt—p. 325

Rare Mechanical Obstetric Obstructions S. Liebmann—p. 330

Blood Pressure and Disturbances of Blood Pressure H. Kahler—p. 337

Epidemics of Meat Poisoning—According to Hammerschmidt, the genesis of food poisoning is not entirely clear as yet. He points out that Gartner's theory is still accepted by many. According to that theory the symptoms of poisoning are the result of toxins that have been formed in the food by a pathogenic organism. This theory would explain that the toxins are thermostabile, that is, that poisoning may result also from foods that have been cooked. On the other hand it has been observed that in the course of meat poisonings those persons became ill who have eaten raw or half raw meat, not however those who have eaten the meat after it has been cooked. The author calls attention to experiments which proved that pathogenic microorganisms were still present in artificially infected meat after ten minutes of cooking. He reports two epidemics of meat poisoning in which the persons had eaten only cooked meat from animals that had been killed because they were sick. The meat had been fresh when sold but in one case the meat as well as the intestine of the cow contained paratyphoid bacteria. In both epidemics the majority of the patients excreted the pathogenic organism in the urine and stool and in many cases the agglutination tests of the serum were positive. It is possible that the appearance of infectious microorganisms in the human body is an accidental occurrence. It is now generally assumed that the acute poisoning is usually caused by the disintegration and decomposition of the meat poisoning bacteria which had entered the body alive together with the food. However in the course of the epidemics of meat poisoning the author observed also patients who had never eaten infected meat and yet they developed the same symptoms of poisoning and the stool and urine contained the same pathogenic organism. From the latter observations he concludes that the cause of such food poisonings must be an infectious one for they cannot be explained by the intake of decomposition products generated in the food by bacterial action.

Rare Forms of Fungous Diseases of Skin A. Musger—p. 365

New Method of Determining Sore's Skin Fold Phenomenon M. Goldstein—p. 367

Electrosurgery in Severe Infections—Mandl employed electrosurgery in fifteen cases. Two patients had old osteomyelitic processes, one a fungous infection of the ankle joint

with fistulas and cold abscesses, six carcinoma that became septic and led to a septic condition, two severe *Bacillus coli* infections, one so called gangrenous erysipelas and three severe infections of the soft parts. One patient of the latter group died. In some cases amputation of an extremity seemed indicated but the use of electrosurgery made it unnecessary. The author stresses the following advantages of electrosurgery: 1. It avoids pressure on the tissues. 2. It produces hyperemia. 3. It closes the blood and lymph channels instantaneously and thus prevents the spreading of infection. 4. The coagulated tissue binds the bacteria. 5. The surgical shock is reduced because electrosurgery prevents resorption. 6. The hyperemia and exudation necessary for wound healing are accelerated and intensified. 7. It is probable that electrosurgery mobilizes the defense powers of the organism. The author concludes that electrosurgery should take the place of ordinary surgery in severe infections.

Division of Pleural Adhesions from Single Puncture—

The Abellos point out that an apparatus for the division of pleural adhesions from a single puncture was first introduced in 1924 by Singer and that later several other appliances were introduced. They consider such surgical thorascopes a considerable advancement in the operative technique. They employed chiefly a modification of the apparatus of Graf. Before giving a description of this instrument, they discuss the preoperative measures. Adhesions that are to be divided are prepared by the so called pneumothorax in short intervals. In this type of pneumothorax the pressure is not increased but is kept for a long time at a minimum. In some instances the authors refilled the pneumothorax every second day. They further discuss the localization of the pleural adhesions reviewing the different methods of roentgenoscopy and roentgenography and emphasizing that the technique of Miñana and Coopestein gives the best results. Then they describe the operative technique, the advantages and disadvantages of Graf's apparatus and how they overcame the latter. The apparatus of Graf has the advantage of permitting the use of various techniques (galvanocautery, diathermic coagulation, high frequency current and so on) in a single intervention. Moreover, of all the devices that operate from a single puncture Graf's apparatus has the largest visual field. However it has the disadvantage that the cautery is too short. The authors lengthened the cautery particularly its point and devised a cautery that could be used with high frequency currents and a galvanocautery. The combined use of these methods reduces the time required for the operation. The authors report a case that illustrates the advantages of the improved technique.

Detection of Tubercle Bacilli in Feces—Piasecka Zeyland and Sznajder examined the feces of sixty tuberculous patients for the presence of tubercle bacilli. Thirty-two of the patients were children with the various forms of tuberculosis, particularly pulmonary tuberculosis and twenty-eight were adults with so called open pulmonary tuberculosis. The authors used the culture mediums of Löwenstein, Petraghiani and Hohn. Each specimen of feces was tested in ten different tubes. The culture medium of Petraghiani proved to be the most satisfactory. The examination of the feces of the adults gave positive results in less than half of the cases (twelve positive results). In the children all the tests on the feces had a negative outcome, although tubercle bacilli had been detected in the gastric contents of seventeen of the children. Thus the tests demonstrate that as regards the detection of tubercle bacilli the examination of the gastric irrigation fluid is superior to that

of the feces. The authors conclude that the examination of the feces is useless in cases in which the other excretions have been found to be free from tubercle bacilli.

Bilirubin Tolerance Test—By means of photometric analysis developed by Heilmeyer, Brochner Mortensen determined that plasma and serum have the same bilirubin content. The normal maximum of bilirubin is 1 mg per hundred cubic centimeters of serum. The bilirubin content is not constant. In the normal person it generally increases during fasting and decreases after eating. The author discusses the theoretical basis and describes the technique of Lilbott's bilirubin tolerance test. He reviews clinical experiences formerly made with this method and then describes the results obtained with the bilirubin tolerance test in twenty-five normal persons in twenty-eight patients with hepatic disorders and in thirteen patients in whom hepatic disease was not quite certain. As an indicator of the functional condition of the liver the test proved slightly more sensitive than the galactose test, the bromsulphalein test and the determination of the quinine resistant lipases. However the method cannot be used in cases of icterus in which bilirubinuria exists.

Ileus Caused by Retention of Iron in Cecum—Sjöberg points out that in cases of anemia with gastric achylia and deficient function of the intestine there is danger of retention of iron when large doses of reduced iron are given. He reports a case of achylia and a tendency to constipation in which a mass of unabsorbed iron accumulated in the cecum led to the development of a concretion, which in turn produced symptoms of ileus. The concretion was visible in the roentgenogram. The patient was treated with laxatives and enemas. The examination of the feces disclosed the presence of iron. Repeated administration of laxatives and enemas finally produced evacuation of stonelike lumps, and after that the symptoms of ileus disappeared. In order to determine whether the retention of iron is a frequent occurrence in anemic patients with achylia who are given large doses of iron the author subjected a number of such patients to roentgen examination. Three patients proved to be free from shadows indicating the retention of iron, but in a fourth roentgenoscopy disclosed signs of retention.

Condition of Heart in Obesity—To determine the relationship between obesity and circulatory disturbances Geill and Secher made studies on ninety-two patients in whom obesity was the only disorder. They found that the heart is enlarged in older patients with obesity, but that the size of the heart decreases after a reducing and rest cure. However, the transverse diameter does not again reach completely normal values. The reduction in the transverse diameter is dependent on the loss of weight. Electrocardiography of these patients gives no indications of the existence of degenerative changes in the myocardium.

- Report on Cases of Acute Hepatitis with Brief and Late Positive Result of Bauer's Galactose Test. T. Geill—p. 305

Stenosis of Aortic Isthmus—In Jacobson's case, necropsy confirmed a presumably congenital stenosis of the aortic isthmus with ectasia of the arch of the aorta and the ascending aorta and hypertrophy of the heart and development of a considerable

collateral arterial circulation. There was stasis in the liver and kidneys, and the immediate cause of death was an effusion of blood within the pericardium. The patient was a woman, aged 35. He says that the following symptoms aid in the diagnosis of congenital stenosis of the isthmus during life: (1) visible and increased pulsation in the three fields where the collateral circulation may develop, (2) poor circulation in the lower part of the trunk and lower extremities, with pallor and anemur and subjective sensation of cold, and with cyanosis in the upper part of the body, (3) possibly stasis albuminuria, (4) retardation of crural pulse and increased blood pressure in the upper part of the body as compared with the blood pressure in the lower part, and (5) the results of roentgen examination.

- Nevi Pigmentosi. Contribution to Understanding of Their Etiology. M. Björneboe—p. 329

Bronze Diabetes—The results of necropsy in Meldahl's cases, observed within little more than a year, showed a typical bronze diabetes. Jaundice, ascites and prominent anemia were absent, except in one case in which ascites appeared during insulin treatment as in the two cases reported by Bingel. The order of development is thought to have been cirrhosis of the liver and pancreas with iron pigmentation, later diabetes and, finally, melanoderma. There were no endocrine disturbances or neurologic complications. The author ascribes the infrequent anatomopathologic diagnosis of bronze diabetes to the omission of microchemical examination, and the more infrequent clinical diagnosis partly to the incorrect impression, from the term 'bronze diabetes' that the diagnosis depends on the presence of both pigmentation of the skin and diabetes, and partly to the lack of means of confirming the diagnosis when bronze diabetes has been suspected a means which in his opinion is afforded by microscopic examination of the skin (demonstration of iron pigmentation).

Nevi Pigmentosi—Björneboe reports a case of extensive nevi pigmentosi in a man, aged 37, combined with neurofibromatosis of the skin and complicated with primary melanosarcoma of the brain. There were hairy nevi on trunk and thighs. The case is explained by the assumption that neurofibromas and melanomas, or neuroplastic sarcomas and malignant melanomas, are of the same nature which in this case seems to be supported partly by the intimate relation between the neurofibromas and the nerve cells, partly by the establishment of autochthonous melanin in a nerve with neurofibromatous changes. The author considers it probable that nevi are an organoid malformation in which both epidermis and connective tissue and presumably the nervous system play a part.

Antianemic Factor in Preparations of Dried Stomach—Meulengracht found that, in pernicious anemia in man, desiccated pulverized preparations from the cardia glands of the stomach of swine possess a certain antianemic effect slight, however, in comparison to that from the pyloric glands. The quantitative difference in the antianemic factor of the two glandular types is explained by the smaller amount of glands per surface unit in the cardia region, roughly from three to five times less than that of the pyloric region. The conception of a fundamental identity between the two types of glands is thus supported at least with regard to production of the antianemic factor. Histologically, the points of resemblance are so marked that the glands may anatomically be regarded as identical. The so-called cardia glands in swine are presumably pylorus glands, which in a manner peculiar to swine extend upward and along the lesser curvature and over a large part of the cardia portion.

Histologic studies of the central nervous system in dementia praecox have failed to reveal specific morphologic nerve changes. Such structural changes as may be present in this morbid condition are secondary. Quite constant, but by no means characteristic, are changes in the cerebral subarachnoid space. The changes may be termed chronic aseptic meningitis in which, among other lesions, there are present hyperplasia of the connective tissue and proliferation of the mesothelial cells. In addition, abnormal microchemical phenomena are demonstrable in the ganglion and glia cells, mainly in the form of lipoids. The aseptic meningitis is to be looked on as a meningeal reaction against toxic substances discharged from the depth of the brain tissues into the subarachnoid space. Though toxins are present also in normal cerebral tissues, they are probably neutralized after they have been removed by the tissue fluids of the brain into the subarachnoid space (by way of the perivascular spaces of Virchow-Robin) and from there to the blood.

Vast and rapid accumulations of toxic substances in the brain may produce profound toxic changes in both the ganglion and glia cells, their destruction with formation of clasmotodendrosis (breaking up of the glia fibers) and ameboid glia (degeneration of the glia cell bodies). However, such changes occur only in peracute toxic states, as can be demonstrated experimentally on animals. In catatonic and other forms of dementia praecox, essentially chronic morbid conditions, acute destruction of the parenchyma and glia does not occur.

One must assume that either accumulation of toxic substances is gradual in these conditions or their elimination defective, and that by increasing the discharge of the problematic toxins one may assist the brain in ridding itself of harmful substances and thus attaining its normal function. This can be accomplished by the method devised by Weed and his

co-workers¹ in changing at will the bulk of the brain. They demonstrated that an intravenous injection of a hypertonic salt solution causes shrinkage of the brain accompanied by lowering of the pressure of the cerebrospinal fluid and that an intravenous injection of a hypotonic salt solution causes increase in the volume of the brain with rise in the pressure of the cerebrospinal fluid. Both these forms of injections have been used in our experiments. They were combined in some instances with continuous or forced drainage, the latter used by Kubie² and others³ in the treatment of various acute and chronic diseases of the central nervous system. We planned experimenting with the foregoing method and its modifications on a large number of patients, but after a careful trial in three patients we found the method in general useless and discontinued it. The reasons for abandoning the method and some observations we made during our studies are of sufficient interest to be recorded.

CASE 1.—A white man, aged 23, was admitted to the Psychiatric Institute of the Research and Educational Hospitals, Oct 28, 1932, in a catatonic state. Prior to admission the patient had been treated in a state hospital with carbon dioxide, radium chloride and many other methods. When admitted to the institute, the patient was mute and negativistic. As his general physical condition grew progressively worse, his parents readily gave permission to experiment with intravenous injections. To ascertain the difference in reactions to various solutions (isotonic, hypertonic and hypotonic) the patient was first given (from Jan 7 to Jan 24, 1933) by Dr Haines three intravenous injections of Ringer's solution (150 cc.) followed by an injection of 50 cc. of 25 per cent solution of dextrose. On two occasions there were flushing of the face, slight twitchings at the corners of the mouth and excessive perspiration. From January 31 to October 26 the patient had been given intravenous injections of 0.45 per cent solution of sodium chloride. In two instances the solution was that of 0.33 per cent and in three instances that of 0.2 per cent. The amounts of fluid injected were from 200 to 2,225 cc., the duration of each injection was from one to two hours. The hypertonic solution used was that of magnesium sulphate (25 cc. of a 10 per cent solution) or dextrose (50 per cent). The injections were given every five or eight days and during the last month (October) were combined with forced drainage of the cerebrospinal fluid, of which from 90 to 150 cc. was withdrawn. The reactions of the patient to the injections of hypotonic

solutions (1,500 cc of a 0.2 per cent solution) were excessive perspiration, occasional cyanosis of the finger nails, flushing of the face, an eruption of an urticarial rash on the face, neck and forehead, chills, a slow, thready pulse and mild hemoglobinuria.

There were no significant changes in the temperature, respiration and for the most part pulse rates. There was always an increase of the systolic blood pressure from injection of hypotonic solution (especially after the completion of the injection), which always dropped to normal within sixty minutes after the injection. The changes in the number of red cells were insignificant. On three occasions their number increased by about 180,000 to 350,000 and in two instances there was an average drop of 365,000. In contrast, injections of hypotonic solutions invariably caused an increase in the white cells. The average increase was 2,900 cells, mainly in the polymorphonuclears. A differential count showed a decrease of lymphocytes, the eosinophils disappeared altogether. The content of nonprotein nitrogen, cholesterol, carbon dioxide and creatinine was reduced, that of total protein and sugar in the cerebrospinal fluid showed no appreciable change.

A slight improvement was noticed in the mental condition of the patient after the first treatments. He came out of the catatonic state, showed some interest in the surroundings and was somewhat cooperative. Ultimately (after about two weeks) he became worse though as a rule, not to the extent of the preinjection severity.

CASE 2—A white man, aged 37, was admitted to the Psychiatric Institute of the Research and Educational Hospitals Aug. 15, 1933, because of an advanced case of dementia praecox (catatonic type). The patient was negativistic and exhibited stereotypes of posture and speech, a practically absolute mutism and some other features of catatonic dementia praecox. Since 1928 there had been progressive emotional deterioration, regardless of the numerous methods of treatment used—injections of carbon dioxide, administration of physiologic solution of sodium chloride by mouth and of globulin extract, and colloidal sulphur injections. After treatment of seven months' duration at the institute, the patient was transferred to the Chicago State Hospital as unimproved. The hypotonic solutions used were those of 0.45, 0.33 and 0.2 per cent. The average amount injected was 1,500 cc. In one injection it was 2,640 cc (0.45 per cent), four injections were of 0.2 per cent and three of 0.45 per cent and one of 0.3 per cent, all without untoward effects. Only in one instance was there cyanosis of the lips and the finger nails, and the urine was blood tinged (in the seventh injection). The blood pressure rose during and immediately after the injection (the highest rise was 24 points) and came down to the preinjection level within ten minutes. The number of red cells dropped on all occasions by 380,000. Once after an injection of magnesium sulphate there was a further drop of half a million. The number of the white cells practically always showed an increase, especially the polymorphonuclears (by 23 per cent), while that of the lymphocytes dropped by 25 per cent. No particular changes were found in the carbon dioxide and calcium content of the blood.

CASE 3—A man, aged 32, was admitted to the Psychiatric Institute of the Research and Educational Hospitals, March 2, 1932, with the classification of schizophrenia (hebephrenic type). Prior to admission he had been unsuccessfully treated for six years at one of the state hospitals with various methods. The patient became untidy, destructive and uncooperative.

The treatment with intravenous injections was begun on March 31, 1933, and was continued for a period of seven months with a three months' interval. Thirteen injections were given, in amounts of from 1,000 to 1,500 cc. of 0.45, 0.33 and 0.2 per cent solutions of sodium chloride. The patient usually tolerated the injections well. In two instances, after an injection of 0.45 per cent solution, he became agitated, complained of warmth and jumped around, the face flushed. The effects of the injections were the same as observed in the two previous patients. The blood pressure rose during and after the injections, in some instances 22 points, the red cells and cholesterol exhibited a slight drop, the white blood cells (the polymorphonuclears) showed an increase and after an injection of 1,500 cc. of a 0.2 per cent solution of sodium chloride the urine appeared

wine colored. As in case 1 there was a temporary improvement in the mental condition but none was noticed from the subsequent treatments.

COMMENT

The three patients represented advanced stages of schizophrenia and, as noted, had not improved under any treatment. For this reason they were selected for the experiments with intravenous injections of hypotonic and hypertonic salt solutions. In the additional use of hypertonic solutions and in the use in some instances of the hypotonic solution only, this method differs from that used by Kubie,² Retan and others³ in organic diseases of the central nervous system. Hypotonic solutions injected into the veins cause, through osmosis, excessive accumulation of fluids in the brain, their flooding, as it were, and increase in the bulk of the brain. A subsequent intravenous injection of a hypertonic salt solution produces, also through osmosis, a reversed action—a return of the excessively accumulated fluids into the blood vessels and the adventitial spaces of Virchow-Robin with the subsequent shrinkage of the brain tissue. Returning to the blood vessels of the brain, the tissue fluids containing the vastly diluted waste products of the cerebral parenchyma are partly absorbed by the blood and partly discharged into the cerebral subarachnoid space. From here they are removed through the perineural channels to the periphery. A veritable lavage of the brain is thus effected, unaccompanied by severe reactions of the organism. The practical absence of complications following injections of 2 or more liters of greatly diluted (0.2 per cent) solutions of sodium chloride is especially noteworthy. However, no striking mental reaction was noticeable, and the therapeutic method, though based on apparently sound experimental and pathologic facts must be considered worthless. The reason for the failure lies in the fact that the problematic toxins of the brain are not removed by the method here described in sufficient quantities to effect either a cure or even a temporary improvement. According to the current teachings⁴ the contents of the subarachnoid space are derived from the choroid plexus and in smaller amounts from the cerebral perivascular spaces of Virchow-Robin. The rapid increase in the amount of fluids in the brain after injections of hypotonic salt solutions and their equally rapid decrease after injections of hypertonic solutions would rather suggest that the entire cerebrospinal fluid is derived from the tissue fluids of the brain.⁵ Reaching the subarachnoid space the fluids are absorbed (according to current teachings) into the vascular system, either by the arachnoid villi or by the perineural spaces of the cerebral blood vessels. The latter mode of absorption is most likely the correct one.⁶ Whatever the theory, the ultimate discharge of the cerebrospinal fluid and the toxic substances is into the vascular system. The forced drainage removes only a small amount of fluid—from 90 cc. to about 150 cc.—against 2 or more liters injected intravenously, and Kubie himself stated that "the possibility that some fluid may become trapped in the system cannot be ruled out by the methods used." Even were it possible to wash out and remove the toxins entirely, one could not pre-

vent formation of new toxic substances, for the exact mode and cause of their formation and their nature are not known. The foregoing considerations seem to present sufficient reasons for abandoning the method of intravenous injections of hypotonic or hypertonic solutions because useless. However, it may yet prove valuable if solutions used are not those of sodium chloride alone but combined with some medicinal substances possessing certain chemical affinity for the nerve elements.

CONCLUSIONS

1 The basis of the method of treatment of abnormal mental conditions with intravenous injections of hypotonic and hypertonic salt solutions is the dilution of the toxins contained in the tissue fluids of the brain and their removal mainly to the subarachnoid space.

2 Large amounts (about 2.5 liters of hypotonic salt solution) can be injected intravenously without harmful effects.

3 The solution of sodium chloride may be as low as 0.2 per cent.

4 The changes in the chemistry and morphology of the blood are mild and transitory.

5 Only a small part of the increased amount of the cerebrospinal fluid formed by intravenous injections of the hypotonic solutions can be removed from the nervous system by forced drainage, the larger portion remaining in the brain and becoming reabsorbed into the general blood circulation.

AN EVALUATION OF DINITROPHENOL AS AN AID IN WEIGHT REDUCTION

JAMES M. STRANG, MD

AND

FRANK A. EVANS, MD

PITTSBURGH

Much attention has been directed in recent years to the reduction of the weight of obese subjects. The removal of fat deposits is dependent on the creation of a deficit between the daily intake and the daily output of energy. This deficit can be obtained either by a reduction of intake or by an increase of output.

In the past year a new group of chemicals, of which the principal one is alpha-dinitrophenol (1-2-4), has been advocated as a method of securing weight reduction by increasing the energy output.¹ These drugs have an advantage over thyroid extract in the absence of certain side reactions such as tachycardia and palpitation. It therefore becomes desirable to discover the practical value of the use of dinitrophenol² by observation of its effect on the weight change of obese patients who have been placed on carefully established regimens and to compare these results with those obtainable by well established dietary procedures.

METHODS

Six patients were studied over periods varying from 54 to 115 days. These patients were all women in good

From the Division of Internal Medicine of the Western Pennsylvania Hospital.

² The dinitrophenol used in this work was supplied to us by the Department of Pharmacology of the Stanford University School of Medicine through the courtesy of Dr. M. L. Tainter.

health apart from the obesity and certain dependent disabilities such as varicose veins and painful knees. They varied from young adult to middle age and from moderately to grossly obese and may be regarded as fairly representative of the average types of obese patients encountered in practice.

The strict technic of the metabolic pavilion governing intake and output of food and residues, which has been described elsewhere, was observed throughout.³ Body weights were taken daily under our "standard" conditions.

On each patient the total periods of study were divided into two parts (A), that in which the patient received a diet of approximately maintenance caloric value, (B) that in which a reduction diet of the type that we have employed for more than seven years was used. In each major division, the patient was established on the dietary regimen for one or more weeks. When the rate of metabolism and the rate of weight change appeared to have become stabilized, dinitrophenol was given in doses up to 300 mg. daily for one or more weeks. The drug was then discontinued and, after subsequent periods of stabilization, employed again. All patients had two periods with dinitrophenol. One patient had four such periods.

Basal metabolism determinations were done as a routine twice a week. Unusual observations were repeated on the following mornings. The Tissot method was used throughout. Body surface measurements were estimated from the Sandiford tables. Most of the data are expressed in terms of total caloric exchange rather than in terms of basal metabolic rate.

The results are tabulated according to the major dietary periods and their successive subdivisions. The maintenance diet period (A) was composed of three subdivisions: (1) stabilization period of maintenance diet without drug, (2) maintenance diet plus dinitrophenol and (3) maintenance diet without drug. Only three patients were observed in the third phase. In the comparative analysis based on data recorded in table 2, the figures for the two drug-free periods taken together are contrasted with those for the dinitrophenol period. The average figures are not weighted, because the distortion resulting is relatively slight and the complete details appear in table 3. In subsequent portions of the discussion, only strictly comparable data are employed.

The reduction diet period (B) was composed of seven subdivisions: (1) reduction diet alone, (2) reduction diet plus dinitrophenol, (3) reduction diet alone, (4) reduction diet plus dinitrophenol—three patients only, (5) reduction diet alone—three patients only, (6) reduction diet plus dinitrophenol—one patient only, (7) reduction diet alone—one patient only. Again, as with the maintenance diet figures, the unweighted data for the four drug-free periods are contrasted with those of the three dinitrophenol periods in the analysis based on the data in table 2. The details of these periods are recorded in table 4. In the subsequent discussion only strictly comparable data are employed.

Each of the subdivisions of these two major periods, namely, maintenance diet and reduction diet, was further divided for purposes of more careful analysis into a first and a second half. It was felt that the heat production data of the successive first half periods were greatly influenced by the lag in the building up of the metabolism to a maximum after the drug was started.

³ Strang, J. M., and Cox, A. B. The Analysis of High Caloric Diets in Relation to Weight Change. *Ann. Int. Med.* 7:152 (Aug.) 1933.

or in the drop from a maximum to a natural level after the drug was stopped. Also, large alterations in water balance which require separate consideration occurred in the first half periods. The decision as to the time of separation of the second halves was of course arbitrary. It was based in part on the demonstration of a rather uniform slope of daily weight curve but more especially on the demonstration of a maximum or a minimum plateau on the curve of basal metabolism. Accordingly, it is felt that the data of the second half periods are as free from controllable extraneous influence as is possible.

RESULTS

The six patients on admission weighed from 77.6 to 150.5 Kg, with an average of 111.8 Kg. They were studied for a total of 437 days, with a range from 54 to 115 days. They lost a total of 99.4 Kg, or an average of 16.6 Kg each. For 190 days of the study the patients received approximately "maintenance" diets, on which they lost 24.8 Kg. For 102 days or

calories and that of less than 600 calories, were greater without the drug than when it was being taken. Attention may also be drawn to the data showing the relation between basal metabolism determinations and the rate of weight loss. As a result of the use of dinitrophenol there was an increase of oxygen consumption. This increase was of approximately the same magnitude (20 per cent) when the drug was given in addition to the maintenance or the reduction diet. The apparent paradox of diminished rate of weight loss with an increased rate of oxygen exchange is discussed later.

For brevity, the details of the individual subjects are arranged in tables according to diet level. Table 3 contains the data of the maintenance diet division (A), of which there were three phases: 1 and 3 without drug, and 2 with dinitrophenol. Table 4 covers the seven phases of the reduction diet periods (B), of which four phases (1, 3, 5 and 7) were drug free and three phases (2, 4 and 6) were with dinitrophenol.

The rationale for subdividing each individual phase of the major dietary periods into a first and second half period becomes more apparent from a study of the superimposed graphs of basal metabolism and daily weight. The curves for one subject, patient 2, which appear in the accompanying chart, indicate chronologically the major dietary periods and particularly the method of identifying the first and second half portions of the individual phases.

SYMPTOMATOLOGY

At the time of admission, our patients had a variety of the usual complaints of obese persons who seek medical aid, such as varicose veins with ulceration, headache, dyspnea on exertion, and pain in the lower part of the back. One patient was recovering from pityriasis rosea. During the period of maintenance diet without drug the majority of these symptoms subsided rapidly, possibly in association with the almost complete physical rest. When dinitrophenol was added to the maintenance diet, the first symptoms noted were warmth of the skin and sweating. Sweating occurred on the first day in one patient and before the eighth day in five patients. Drenching night sweats occurred in four patients from the fourth to the tenth day. Day sweats were noted by three patients but were less frequent than the night sweats. The sweating was not continuous. After several nights of profuse sweating, intervals of several days elapsed with relatively little sweating before the return of the drenching sweats. One patient had no sweating. No itching was experienced by three patients. One patient had moderate itching for only two days. One patient had a severe dermatitis, which began on the tenth day. Three patients had headache after the seventh and tenth days. One patient had nausea and dizziness for several days, another had epigastric pain for from two to three days before the drug was stopped. After the drug was stopped the symptoms diminished rapidly. No sweating was noted after the second day. Headaches continued in two patients at intervals. One patient had itching for most of the post-drug interval. The same patient also had many nervous manifestations such as precordial distress and choking spells, which were probably quite unrelated to the use of the drug.

When the dinitrophenol was started for the second time, this time in association with the reduction diet, cutaneous manifestations promptly returned. Sweating was noted in only four patients. Three patients had one or more profuse night sweats from the fifth to the

Daily weight and basal metabolism of patient 2 by diet and by drug periods. The weight is indicated by the solid line and the basal metabolism calories per hour by the broken line.

54 per cent of this period, they received an average daily dose of 250 mg of dinitrophenol. In the remaining 247 days in which they were on "reduction" diets they lost 74.6 Kg. For ninety days, or 36 per cent of this reduction diet period, they received an average daily dose of 290 mg of the drug. The averages of the individual rates of weight loss were 130 Gm per day and 290 Gm per day, respectively, for these two periods (table 1).

In table 2 the data are divided into four periods:

- 1 Maintenance diet without the drug
- 2 Maintenance diet with the drug
- 3 Reduction diet without the drug
- 4 Reduction diet with the drug

The data in this table are further subdivided for reasons already given into first and second halves for each of these four periods. Without discussing the various details presented in this table, it is observed that, however subdivided and compared, the rates of weight loss with both diets, that of more than 2,500

ninth day One patient had a single massive sweat on the sixth night only Itching was much more serious in this period On two patients an acute dermatitis developed which required the stoppage of the drug In one case a rash appeared on the arm on the fifth day, which in two days extended over the shoulder In the other case an intense generalized rash appeared on the ninth day Three other patients had moderate to severe pruritus beginning from the first to the fifth day of the drug Patient 3 continued to have attacks of smothering at intervals of several days

The skin reactions subsided after the drug was stopped, but much less promptly than on the previous occasion No sweating was noted after the second day In the three patients with moderate itch, this symptom diminished rapidly after the first day In patient 6 the dermatitis progressed for four days after the drug was

RELATION OF ENERGY BALANCE TO RATE OF WEIGHT LOSS

In viewing the problem of the removal of excess weight in obesity, one should keep in mind its intrinsic nature, that is, what is to be removed The excess weight consists of small amounts of supporting tissue and considerable water, but chiefly of fat There is no evidence that this fat differs basically from other natural fats, and consequently each gram contains 9.3 calories of potential energy Weight changes can be effected by the removal of any of the component substances What is measured by the scale is the residual balance of all substances quite without regard to the type of material In other words, the scale does not discriminate between the removal of 5 pounds of water and 5 pounds of fat Rapid large weight changes are usually transient and are due chiefly to alterations in

stopped, covering at its maximum nearly the whole body It then subsided rapidly Patient 5 began to have attacks of acute urticaria, which subsided after the fourth day She was found to be sensitive to mushrooms, although the role played by this food in the attacks is questionable

Three patients received a third course of dinitrophenol, this time also in association with a reduction diet One patient had no sweating, and a second had drenching sweats for one day and two nights The third patient sweat profusely at intervals after the fifth day Two patients again experienced severe itching, which started on the second and fourth days and lasted throughout the remainder of the respective periods These phenomena subsided promptly after the drug was stopped

A single patient was given a fourth course of dinitrophenol It is interesting to note that whereas this patient had experienced considerable difficulty in previous courses with sweating and itching, on this occasion she had no itching and very little sweating

the water content of the body Permanent reductions of weight involve the removal of fat The only non-surgical method of removing fat from the body is by oxidation

The amount of fat that may be oxidized in any period is limited by the balance of the energy output and intake of the period—in other words, the rate of fat loss is directly proportional to the caloric deficit The total amount of fat that may be lost depends on the time through which the caloric deficit persists It is self evident that in order to secure a large weight change in a comparatively short time the maximum possible caloric deficit should be secured

The high level of energy exchange in the obese has been frequently reported In this series of patients, the average basal metabolism (twenty-three determinations) for the first seventy days of study during which the patients received a maintenance diet without drug was 77.6 calories per hour, which corresponds to an average basal metabolic rate of +2 per cent However, in comparison with the metabolism that these

patients would have if they were of normal weight, this basal metabolic level is elevated 31 per cent

Certain information regarding the total metabolism may be obtained by noting the weight changes observed in the period of maintenance diet without drug. In this seventy day period the patients lost an average of 84 Kg while sitting around a ward doing nothing but sewing and reading and at the same time eating an average of 2,510 calories per person daily. If it is objected that these figures for weight loss include the large water shifts that have often been noted in the first few days of hospitalization, only the last thirty-four days of this seventy day period may be considered, in which the patients lost 2 Kg. In this second half period of thirty-four days the patients lost an average of 50 Gm per person daily, which indicates that the total metabolism was somewhat in excess of the caloric

calories if it is assumed for practical purposes that the 2,510 caloric diet was a maintenance diet. If it is considered that this caloric deficit was supplied by fat alone, 210 Gm of fat would be required, which is equivalent to 240 Gm of fatty tissue. The average of the rates of weight loss actually observed for this thirty-two day period of reduction diet was 300 Gm per day, with surprisingly little individual variation from the average. If the average of the rates of weight loss of the thirty-four days of maintenance diet, 50 Gm per day, is subtracted, the difference is 250 Gm, which may be compared with the value estimated from the probable caloric deficit, 240 Gm per day. An agreement of this order may be considered as strong supporting evidence that the principal factor regulating the rate of fat loss from the body is the magnitude of the caloric deficit.

* Interpolated

intake of 2,510 calories. However, the basal metabolism averaged 1,850 calories in twenty-four hours, or more than 70 per cent of this minimum estimation of total energy output. This magnitude of the energy exchange of obese persons who are so much at rest that the energy of the combined specific dynamic action, work and nonwork fractions of daily metabolism totals only 680 calories per day is not generally appreciated.

The close relation that exists between caloric deficit and rate of weight loss is indicated by a comparison of the initial seventy day period of maintenance diet without drug and the first period of sixty-three days of reduction diet without drug. In order to minimize the large water shifts at the outset of the former period due to hospitalization and at the outset of the latter period due to the sudden transition to a highly ketogenic metabolic mixture, only the second and more stable halves of these respective subdivisions may be compared. The average intakes for these half periods of thirty-four and thirty-two days respectively were 2,510 and 540 calories—an average daily deficit of 1,970

CALORIC DEFICIT OBTAINABLE WITH DINITROPHENOL AND CONSEQUENT PROBABLE RATE OF WEIGHT LOSS

Methods of securing large caloric deficits consist of those which reduce the intake and those which elevate the output of energy. The preceding paragraph summarizes the results obtainable by reduction of intake. Dinitrophenol is employed to elevate the output of energy. First of all it is desirable to approximate the caloric deficit theoretically obtainable by the drug and the theoretical rate of weight loss resulting. In this connection it is necessary to make two assumptions, the correctness of which we seriously question: (1) that dinitrophenol produces no qualitative alterations in the oxidation processes of the body, and therefore (2) that it causes no interference with the estimation of heat production from a measurement of oxygen consumption and carbon dioxide production in which the standard correlation tables are used. What alteration in energy exchange could be attributed to dinitrophenol? Unfortunately no data on the total metabolism

of the drug periods are available nor can they be approximated from our studies, because of the shifts in water balance. However, the basal metabolism of these patients probably constituted more than 70 per cent of the total metabolism in the period of maintenance diet without drug. It may therefore be considered that the effect of the drug on the basal metabolism will reflect its chief effect on the total metabolism. The average basal metabolism was 769 calories per hour in the latter thirty-four days of the first seventy

above the drug-free levels. The total effect in twenty-four hours of such a caloric increase is less than 450 calories, a caloric effect that corresponds to 48 Gm of fat or 55 Gm of fat tissue. The caloric increments due to the influence of dinitrophenol on the other fractions of total metabolism cannot be estimated but would probably be small.

In other words, the caloric deficit that can be produced by the elevation of metabolism which results from full therapeutic doses of dinitrophenol is some-

day period of maintenance diet without the drug, at which time the curves of basal metabolism were consistently flat at a minimum level. In contrast, in the latter 49 days of the 102 day period of maintenance diet with dinitrophenol the basal metabolism curves maintained a maximum plateau at 929 calories per hour. For the corresponding latter portions of the first periods of reduction diet without drug and reduction diet with drug, thirty-two and twenty-seven days respectively, the minimum level was 730 calories per hour and the maximum drug-effect level was 905 calories per hour. The difference between these minimum and maximum levels, 160 and 175 calories per hour respectively, are increases of 21 and 24 per cent

where around 500 calories per day. Such a deficit could produce a loss of only 60 Gm (2 ounces) of fat tissue per day. When it is recalled that our patients in the thirty-four day half period previously described, in which they received the so-called maintenance diets of 2,510 calories without drug, actually lost weight at the rate of 50 Gm per day, it may be appreciated that the same rate of weight loss which is possible as a result of the use of dinitrophenol can be accomplished by only very slight modifications of the diets on which these persons have been maintaining their weights. In any event, the rate of weight loss obtainable by use of the drug is only from one fifth to one sixth of the rate of loss that is readily obtainable by diet alone.

EFFECT OF DINITROPHENOL ON OXYGEN
CONSUMPTION

With the figures dealing with the results that are theoretically possible from the use of the drug kept in mind, it is now important to discover what action dinitrophenol did have in our patients with respect to (1) basal metabolism, (2) skin changes and (3) rate of weight loss. In each patient in each dinitrophenol period there was a definite increase in the calculated basal metabolism. As aforementioned, the comparisons are made between the maximum plateaus of the curves of basal metabolism that occur in the latter halves of the dinitrophenol periods and the basic minimum levels of these basal metabolism curves in the latter portions of the preceding drug-free periods. In the majority of individual instances there was an elevation of calculated metabolism of from 7 to 18 calories per hour. The average elevation for six patients on the maintenance diet phase was 16 calories per hour. In the reduction diet phases, six patients increased the metabolism 17.5 calories per hour in the first dinitrophenol course, three patients, 20 calories per hour in the second course of the drug. Four patients obtained approximately the same increase in metabolism in successive dinitrophenol periods. However, all these calculations are based on the assumption that the increase in oxygen consumption which is actually observed bears the same relation to heat production that has been found in normal body metabolism.

This matter cannot be fully discussed at this time but there are many observations that cast suspicion on this basic assumption. The absence of alterations of pulse rate and blood pressure is noteworthy, even in the presence of basic metabolic rates that calculate from 70 to 80 per cent above the normal for the ideal weight of an individual. Very low respiratory quotients, several ranging from 0.60 to 0.52, have been noted especially in the low diet periods. These low respiratory quotients have been found in association with the highest basal metabolism calculations. In certain instances the elevation of the respiratory quotient to normal limits by the feeding of dextrose has resulted in a marked drop in the calculated heat production. Also acetone bodies have been found repeatedly in the urine under these conditions. These observations, taken in conjunction with the peculiarities of weight change that are described later, suggest that the drug may produce a qualitative alteration in the usual relationships of heat production to oxygen consumption and carbon dioxide production. If, therefore, oxygen may be consumed in some unusual manner, it is possible that the estimation of heat production by the indirect procedure of the measurement of oxygen consumption may not be permissible.

EFFECT OF DINITROPHENOL ON SKIN

The untoward actions of dinitrophenol have been repeatedly described. The outstanding manifestations in our patients were cutaneous—warmth, sweating, pruritus and dermatitis. Sweating was most profuse in the period of dinitrophenol plus maintenance diet and definitely less in the subsequent periods, being absent in the fourth dinitrophenol period of patient 1. The sweating appeared in most cases before any significant elevation of the basal metabolism occurred. It was intermittent in most cases with respect to both time of day and day of drug. At the time of an acute attack, beads of perspiration ran from the body. Often the

gowns and bed linen was changed two or three times at night. However, one patient who had a satisfactory elevation of basal metabolism in each of two periods had no sweating at all. It is open to question whether such excessive sweating is simply a manifestation of heat elimination or whether there is not a specific stimulation of the sweat glands. Pruritus was present in all subjects at some time. Although of little importance in the period of the maintenance diet with drug, it was very serious in four of the patients in the first period of the reduction diet with drug. In spite of the unusual attention that was given to the skins of these patients, in three patients extensive dermatitis developed, which necessitated stopping the experiment in two patients. It is also important to note the prompt cessation of the sweating and pruritus after the drug was discontinued. No symptoms other than cutaneous were noted that could consistently be attributed to the use of the drug.

EFFECT OF DINITROPHENOL ON RATE OF
WEIGHT LOSS

In the evaluation of the effect of dinitrophenol on the rate of weight loss, several factors must be considered. First of all, it may be noted that at the time at which the metabolism was stable at a maximum level due to the drug there was no increase in rate of weight loss as compared with the immediately preceding drug-free period in which the metabolism was stable at a minimum level. Observations are available of sixteen individual instances in which the rate of weight change in the latter part of a drug-free period of minimum metabolism may be compared with the rate of weight change in the latter part of the dinitrophenol period of maximum metabolism immediately following it. Six instances A_1 latter half with A_2 latter half, six instances B_1 with B_2 , three instances B_3 with B_4 , one instance B_5 with B_6 (tables 3 and 4). Ten phases with the drug showed drops in rate of weight loss of from 10 to 320 Gm averaging 100 Gm daily. One period showed no change. Five periods with drug showed increases from 10 to 110 Gm, averaging 60 Gm daily. The average of all sixteen periods shows a decrease of 10 Gm daily as a result of the use of the drug. Here is an apparent paradox that with the increase in the oxygen consumption, the rate of weight loss decreases, and this in spite of terrific outpourings of sweat in some patients.

A partial explanation of this phenomenon is that the drug promotes the storage of water. Whether or not this storage results from direct toxic injury to the cells causing cloudy swelling cannot be decided as yet. The water storage phenomenon is most clearly visualized from the graphs of weight and of metabolism as illustrated in the chart. The slopes of the weight curves almost invariably flatten toward the middle of the dinitrophenol periods. The flat period is usually followed by a sharp drop in weight within one to two days after cessation of the drug. These facts are indicated less graphically by a comparison of the rate of weight change in the first half of a drug-free period with that of the second half of the preceding drug period. In twelve instances, data are available for the comparison of such successive half periods. Three instances A_2 latter half with A_3 first half, six instances B_2 with B_3 , three instances B_4 with B_5 (tables 3 and 4). For these twelve cases there was an average increase in rate of weight loss of 130 Gm per day after the drug was stopped. In two instances there were decreases, in

one, no change, and, in nine, increases which in one case amounted to 500 Gm per day. It should be noted that in the contrasted periods there were only slight variations in caloric intake and that in the periods of increased weight loss the metabolism was dropping rapidly to the basic level.

However, it still remains possible that the rate of fat destruction is actually increased in the dinitrophenol periods and that this phenomenon is obscured by the water storage. If that is true, the weight change in the latter part of a dinitrophenol period plus the weight change of the first part of the succeeding period in which water is poured out, divided by the total number of days, should give a rate of change greater than the rate in the basic drug-free period immediately preceding the dinitrophenol period. There are twelve individual instances in which it is possible to compare the rate of weight change of the stable latter part of a drug-free period with the rate of change of the combined phase of maximum drug effect and the phase of water release that follows immediately. Three instances A_1 latter half with A_2 latter half plus A_3 first half, six instances B_1 with B_2 plus B_3 , three instances B_4 with B_5 plus B_6 (tables 3 and 4). Of the twelve instances, six showed slightly greater and six slightly lessened rates of weight change in the dinitrophenol period as compared with the drug-free period. The value of the average deviation from the mean for these twelve observations is negligible. Our figures suggest, therefore, that dinitrophenol does not cause an increase in the rate of weight loss. Rather the use of the drug decreases the preexisting rate of weight loss, owing probably to its influence on the phenomenon of water storage. However, when the excess stored water is removed, as usually occurs within a few days after the drug has been discontinued, it is found that in the majority of instances no significant change has occurred in the rate of true weight loss that was characteristic of the dietary level employed before and during the dinitrophenol phase.

The influence of dinitrophenol on the nitrogen metabolism could not be determined in this study. The level of nitrogen intake was constant throughout the entire stay of the patients. The nitrogen in the urine and stools was determined for each three day period. In general, this nitrogen output approximated the intake. However, during the periods of gross sweating considerable nitrogen must have been lost through the skin. It is interesting to note that sweating had no consistent influence on the urinary nitrogen.

SUMMARY

In our patients, dinitrophenol in therapeutic doses produced an increase of oxygen consumption of approximately 20 per cent. Whether this disappearance of oxygen is a reflection of increased heat production or whether there is an alteration of the normal oxygen utilization due to the toxic action of the drug is not clear. It appears that there is a tendency of the body to store water under the influence of the drug. The drug readily produces skin reactions varying from moderate warmth and sweating to a toxic dermatitis. The question of a specific action on the sweat glands has been raised. The skin actions do not parallel the amount of drug ingested or the level of increase of oxygen consumption. As a method of producing weight loss by increasing the rate of energy output, the drug leaves much to be desired theoretically. Practi-

cally, in our series of patients no consistent augmentative effect of the drug on the rate of true weight loss could be demonstrated in association with either the maintenance or the reduction diets employed in this study.

CONCLUSIONS

1 The rate of true weight loss in obesity is determined by the difference between the intake and the output of energy.

2 The influence of dinitrophenol on the negative energy balance is small in comparison to what can be secured by even moderate diets.

3 The practical value of dinitrophenol as an aid in weight reduction is very questionable and, in view of the well known toxicity of the drug, its widespread use for this purpose should be discontinued.

A QUANTITATIVE STUDY OF THE VASOCONSTRICTION INDUCED BY SMOKING

R STARR LAMPSON, M.D.
BOSTON

Since Buerger¹ described the disease that bears his name there has been controversy concerning the significance of smoking as a factor² in the cause and progress of the symptoms in thrombo-angitis obliterans. Until recently, slight experimental attention had been given

Fig 1—Diagram of apparatus

to the effect of smoking on the peripheral vascular system. The studies dealing with these reactions indicate that vasoconstriction is induced by the use of tobacco. A fall in peripheral skin temperature after smoking has been reported by Maddock and Collier,³ by Barker⁴ and by Wright and Moffat.⁵ These reports, as well as the volumetric studies of Simici and Marcu⁶

From the Surgical Laboratories of the Harvard Medical School at the Massachusetts General Hospital.

and of Bruce, Miller and Hooker⁷ have shown quite convincingly that there is a decrease in the peripheral circulation during smoking. The experiments here reported were undertaken in an attempt to make a quantitative estimate of the reduction in the peripheral blood flow and to observe the duration of this reaction.

METHOD

The determinations of the rate of peripheral blood flow in man were made by recording the changes in the hand volume. The apparatus, designed by Freeman,⁸

Fig. 2—Effect of inhaling one cigarette. In all the graphs the black line indicates blood flow in cubic centimeters per minute per hundred cubic centimeters of hand and the dotted line indicates the peripheral skin temperature.

was a modification of the technic described by Hewlett and Van Zwailuwerberg.⁹ The purpose of the apparatus was to measure accurately the rate of increase in the hand volume that followed the occlusion of the venous return at the wrist. The essential parts consisted of a water plethysmograph for the hand, a Brodie¹⁰ bellows, which recorded the changes in volume on a moving smoked drum, and a narrow blood pressure cuff about the wrist, which could be suddenly inflated from a pressure bottle. As the pressure in the cuff was below diastolic blood pressure the arterial inflow was unimpaired, so that the immediate increase in the hand volume was an accurate index of the rate of blood flow. The rate of the peripheral blood flow was computed from the drum and expressed as cubic centimeters of blood flow per minute per hundred cubic centimeters of hand volume.

The subject of the experiment lay on his back with his right hand in the apparatus. He was clothed and was covered with a thin woolen blanket. The room temperature was kept at about 23°C and the water bath was at hand temperature, which is usually between 30 and 33°C. Psychic stimuli were excluded as far as possible. For the first half hour of each experiment,

records were made to determine the normal blood flow. The patient then smoked, and further records were made during and after the period of smoking. The skin temperature of the fingers or toes was noted with a Tyco's dermatometer.¹¹ The blood pressure and pulse were also recorded. Fifteen normal men (mostly medical students) and five patients from the peripheral circulatory clinic of the Massachusetts General Hospital served as subjects. All were habitual smokers but had not smoked for at least three hours before the experiment. Four common brands¹² of cigarettes and one brand of "denicotinized" cigarette¹³ were used. There were eighteen experiments with cigarettes, five with a pipe and one with a cigar.

RESULTS

The results were uniform and, with one exception, showed a marked reduction of the peripheral circulation both in normal individuals and in patients with thrombo-angitis obliterans.

Effect of Inhaling Cigarettes—The first group of tests was made with normal subjects to observe the effect of inhaling one cigarette. Figure 2 illustrates a characteristic result. The subject of this experiment was a medical student, aged 20, who habitually smoked and inhaled from twenty to twenty-five cigarettes a day. The graph shows a sudden drop in the rate of the peripheral blood flow during the period of smoking, and at the end of forty minutes the flow was still partially depressed. There was a rise in blood pressure from 100/65 to 112/70 millimeters of mercury. The heart rate increased from 52 to 60 beats per minute. Four similar experiments showed a decrease in blood flow ranging from 57 to 83 per cent. In two cases the response lasted fifty-five minutes, and in two cases the experiment was concluded in forty minutes after smoking while the blood flow was still reduced. The greatest rise in systolic blood pressure was 20 mm. of mercury, and the smallest 10. The increase in heart rate ranged

Fig. 3—Effect of inhaling two cigarettes fifty minutes apart.

from 6 to 20 beats per minute. All the subjects showed a drop in peripheral skin temperature.

In order to observe the effects of successive cigarettes, two experiments were conducted while a patient smoked and inhaled two cigarettes fifty minutes apart. Figure 3 gives the results of one of these tests. The subject of these experiments was a patient, aged 33, both of whose feet had been frost bitten fifteen months previ-

ously The toes had been amputated at that time Two weeks before the present entry, pain and infection developed in the left foot Smoking produced a decrease in the peripheral circulation after each cigaret Following the first the blood pressure rose from 102/70 to 115/80 mm of mercury, and the pulse rate from 82 to 90 beats per minute, after the second the blood pressure went from 110/80 to 118/80, and the heart rate from 82 to 92 The graph also shows a slight reduction in the flow while the subject was holding the unlighted cigaret Fifteen minutes after smoking, the

Fig 4—An atypical reaction showing an increase in the peripheral blood flow

In one subject, however, there was a fourfold increase in the peripheral blood flow, following the inhalation of one cigaret Figure 4 shows this experiment The subject was a medical student, aged 25, who never inhaled and who smoked only four or five cigarettes a week He experienced marked sensations of dizziness during the experiment The heart rate went from 76 to 84 beats per minute, and the blood pressure from 108/70 to 120/70 mm of mercury The reaction lasted twenty-eight minutes Such a response is distinctly unusual but has been observed by Simić and Marcu,⁶ and also by Moffat¹⁴ in three out of 130 cases

Inhaling versus Noninhaling—A group of experiments was conducted to determine the difference in reaction between inhaling and not inhaling Three medical students and one patient with thrombo-angitis obliterans, which was limited to the feet, were tested In each case the first cigaret was not inhaled and the second was inhaled to a degree customary for the subject When the cigaret was not inhaled there was a vasoconstrictor response, but the reaction lasted for only fifteen minutes The changes in heart rate and blood pressure were insignificant When the second cigaret was inhaled there was a marked blood flow reduction, which lasted over one hour The pulse went from 66 to 88 beats per minute and the blood pressure from 96/70 to 108/80 The graph (fig 5) also shows slight vasoconstriction associated with pain in the foot following the first cigaret

Three normal subjects who were tested reacted in a similar manner Figure 6 illustrates one of these experiments

"Denicotinized" Cigaretts—In order to determine whether the reaction to smoking could be correlated

patient complained of pain in his foot This was accompanied by a further vasoconstriction At the end of the experiment, thirty minutes after the second cigaret had been smoked, the flow was 60 per cent below the original level

Out of the twenty individuals tested, all but one showed a clear cut vasoconstrictor response

with the amount of nicotine in the tobacco, experiments were conducted with "denicotinized" cigarettes The brand used contained 0.79 per cent nicotine as contrasted with 2.0 per cent nicotine present in the average cigaret¹⁵ One ordinary cigaret weighing about 1 Gm would contain roughly 20 mg of nicotine Baumberger¹⁶ has shown that nicotine occurs in the smoke to the extent of 0.57 per cent of the weight of the tobacco Of this, 88.2 per cent is absorbed on inhaling¹⁷ This means that the smoker retains between 2 and 3 mg of nicotine from inhaling one cigaret Figure 7 gives the reaction of a normal subject, aged 32, while smoking a "denicotinized" cigaret without inhaling There was no vasoconstrictor response The inhalation of a second treated cigaret induced a slight reduction in the peripheral blood flow, which returned to normal in fifteen minutes The pulse rate and blood pressure remained constant When an ordinary cigaret was inhaled there was a marked reduction in the blood flow, which after twenty minutes was still greatly depressed The blood pressure rose from 100/60 to 110/75 mm of mercury, and the pulse from 54 to 60 beats per minute There were four experiments of this type, which demonstrated a shorter vasoconstrictor response with the "denicotinized" cigarettes than with the other brands

Pipe Smoking—Five tests were carried out while the subject smoked a pipe Three were normal individuals and two were patients with thrombo-angitis obliterans The results were not as conclusive as with cigarettes, probably because of the difference in the way each individual smokes a pipe In each case there was a moderate reduction in the blood flow during puffing on a pipe There was no change in heart rate or blood pressure One of the subjects with thrombo-angitis obliterans inhaled the smoke and demonstrated the same sudden vasoconstriction that follows inhaling a cigaret

Fig 5—Inhaling versus not inhaling in a patient with thrombo-angitis obliterans

Cigar Smoking—One experiment done while a normal subject smoked a cigar showed a 30 per cent reduction in blood flow during puffing and a 75 per cent reduction after moderate inhalation of the smoke

14 Moffat, Dean Personal communication to the author

Effect on Patients with Thrombo-Angitis Obliterans
—There were five experiments carried out on patients with thrombo-angitis obliterans, which chiefly involved the feet. All demonstrated the characteristic vasoconstrictor response (fig 5). The reaction was similar in degree and duration to that obtained in normal subjects. One patient, however, differed slightly from the rest in that there was only a 20 per cent reduction in the blood flow, which returned to its previous level in twenty minutes. In this case there was a large element of vasospasm, as indicated by the marked rise in skin temperature after paravertebral procaine hydrochloride block done by Dr J C White. It is quite possible that chronic vasospasm may modify the characteristic acute vasoconstrictor response to smoking.

COMMENT

These experiments have shown that smoking brings about a sudden marked reduction in the rate of the peripheral blood flow, an elevation of blood pressure, and an increase in heart rate. Haggard and Greenberg¹⁸ have recently observed that smoking also elevates the blood sugar level. These reactions, induced by smoking appear to be manifestations of the response of the sympathetic nervous system to mild stimulation. In all the experiments, the blood flow reduction was greatest immediately after smoking. The degree and duration of the vasoconstriction could be correlated with the amount of nicotine absorbed. When a cigaret was inhaled, the rate of peripheral blood flow was at least halved and remained partially depressed for about sixty minutes. If the smoke was not inhaled, the

There is no evidence from these experiments that smoking is an etiologic factor in thrombo-angitis obliterans, but it seems clear that smoking must have a deleterious effect on patients who have already acquired the disease. If such a patient should smoke one cigaret an hour he would depress his peripheral circulation during the entire day. It is of the utmost importance that patients with thrombo-angitis obliterans should

Fig 7—Denicotinized cigaret followed by an ordinary cigaret.

forego the use of tobacco, as it adds unnecessary insult to the already existing injury by further increasing the peripheral circulatory insufficiency.

CONCLUSIONS

- 1 Smoking and inhaling cigarets causes a sudden marked peripheral vasoconstriction, which lasts for about sixty minutes.
 - 2 Cigarets when not inhaled produce vasoconstriction but the reaction lasts only fifteen minutes.
 - 3 A "denicotinized" cigaret produces less effect than an ordinary cigaret.
 - 4 Cigar and pipe smoking also induce vasoconstriction.
 - 5 Patients with thrombo-angitis obliterans respond in the same manner as normal subjects.
 - 6 Smoking is contraindicated in patients with peripheral vascular insufficiency.
- Massachusetts General Hospital

Fig 6—Inhaling versus not inhaling in a normal subject aged 26

vasoconstrictor response was almost as great but the reaction lasted only fifteen minutes. "Denicotinized" cigarets produced a less marked and shorter response than ordinary cigarets. Pipe smoking gave rise to moderate vasoconstriction during puffing and to a marked reaction after inhaling the smoke. One experiment with a cigar demonstrated the vasoconstrictor response. Patients with thrombo-angitis reacted to smoking in the same manner as the normal subjects.

Knighted for Removing a Wen.—Sir Astley Cooper, the greatest and most active London surgeon of the first quarter of the nineteenth century, was an anatomic enthusiast. Cooper, in 1794 at the age of 16, was apprenticed to Mr Henry Cline, a surgeon and teacher of anatomy at St. Thomas's Hospital. A fellow student of these days told "Mr Cline's class now became so large as to crowd and make the dissecting room uncomfortable. Astley disliked this, since it hurried our work, and he suggested that we should remove our subjects to Mr Cline's house, with whom we also resided. The room Astley and I occupied was in the front of the house, with only one window in it. Here we carried on our dissections without interruption for the remainder of the winter. This zeal for dissection remained with Sir Astley (he was knighted because he successfully removed a wen from the scalp of George II) throughout his life, and even after he became the great surgeon of Guy's Hospital he continued daily to dissect at his home.—Guttmacher, A F. *Bootlegging Bodies: A History of Body-Snatching.* Bull Soc M Hist Chicago 4:353 (Jan) 1935.

EXTENSIVE DIPHThERITIC MEMBRANES REMOVED AND PHOTOGRAPHED

MYRON G. TULL, MD
Superintendent Sydenham Hospital
BALTIMORE

The word diphtheria brings to mind a picture of an infection of the pharynx, nose or larynx. Pieces of diphtheritic membrane in the form of casts of the trachea which at times show the beginning of the bifurcation, are frequently knocked loose and expectorated during the process of intubation. To acquaint the profession with the fact that the diphtheritic infection can extend even beyond the tracheal bifurcation is my purpose in this report of two cases.

CASE 1—G. C., a white boy aged 6½ years was brought in a moribund condition, Oct. 27, 1934 to Sydenham Hospital, the communicable disease hospital of the Baltimore City Health Department. The child came from a neighboring rural area. The temperature was 98 F (rectal), the pulse was so rapid and thready that it could not be counted and respirations were uncountable. The child's face was cyanotic, the lips were blanched and he was gasping and fighting for breath. Laryngeal intubation was performed, but the O'Dwyer tube became blocked and it was necessary to remove it at once. A fresh tube was inserted giving the child only a fair degree of relief from the dyspnea, yet he was so much improved over his condition on admission to the hospital that it was decided to await further developments. Sixty thousand units of diphtheria antitoxin was given intramuscularly and 10,000 units in dextrose intravenously. Cultures from the nose and throat were taken. The patient was put to bed under the ordinary nursing care for a diphtheria patient.

Eight hours following the intravenous dextrose and antitoxin the temperature rose to 103.6 F (rectal), the pulse dropped to 140 and the respirations came down to 30 per minute.

On examination of the blocked laryngeal tube, it was found to be occluded by a piece of membrane that extended nearly the whole length of the lumen of the tube. A piece of this membrane was placed in a tube of Loeffler blood serum and incubated.

An attempt was then made to obtain a history of the onset which brought out the fact that the child apparently had been all right until the night before admission. The parents had noticed that he could not breathe properly at that time and called a physician who prescribed for the boy and told the parents to call him if the child was not better in two hours. After vomiting induced by the medicine prescribed the child was slightly better and the physician was not called until the next morning. On responding to this call the physician found the child in a moribund condition and rushed him to the hospital.

The child's father, on being questioned a little more carefully, stated that the boy had been suffering with a cold for several days. Since he did not appear feverish seemed to be playing normally and attended school as usual, little attention was paid to the fact that he had a cold. Even when his voice became hoarse his condition was not considered of serious import nor was medical aid sought until real difficulty in breathing developed. The questioning further brought out that the boy had not been immunized against diphtheria either by toxin antitoxin or by toxoid.

The child passed the first night in the hospital breathing harshly and exhibiting a considerable degree of respiratory pull but showing evident relief because of the intubation. About 9 o'clock the next morning, October 28, more marked difficulty in breathing was present. It was noticeable that there was greater difficulty in exhaling than in inhaling. Extubation was done but his respirations were even more labored without the laryngeal tube than with it so intubation was done again. As this procedure did not help and as he was beginning to show marked cyanosis it was determined to do a tracheotomy.

A medium low tracheotomy was rapidly performed. Just about the time the trachea was opened, the respirations ceased. Spreaders held the cut in the trachea open and artificial respiration was begun. Stimulants were given intramuscularly and epinephrine hydrochloride intracardially, and suction was applied directly into the trachea. It was found impossible to force air into or out of the lungs, and the child died on the table.

After death an examination was made through the tracheotomy opening and by means of a pair of forceps a piece of membrane was delivered into the wound. By carefully and gently pulling and teasing the cast of the bronchial tree as shown in figure 1 was brought through the wound. This explains fully why it had not been possible to force air into the lungs, although there was an opening in the trachea sufficiently large to do so.

The cultures taken from the nose, the throat and the piece of membrane after incubation over night were reported from the laboratory as positive for the Klebs-Loeffler bacillus.

Fig. 1 (case 1)—Diphtheritic membrane removed after death.

CASE 2—H. G., a white girl aged 9 years, admitted to Sydenham Hospital Jan. 27, 1935, was in an extremely toxic condition. Like the preceding patient, she was a county child brought to the city for hospitalization. While she was breathing noisily and her color was somewhat cyanotic, no operative intervention was deemed necessary as she seemed to be getting a sufficient amount of air through the partly obstructed air passage.

She had received 20,000 units of diphtheria antitoxin prior to being sent to the hospital. On admission the temperature was 104.4 F (rectal), pulse 150 and respirations 40. A second dose of 20,000 units of diphtheria antitoxin in dextrose was given intravenously and this was followed by 40,000 units intramuscularly. Cultures of the nose and throat were taken and sent to the laboratory. The child was put to bed under constant nursing supervision. She did not respond to treatment but gradually became worse and died January 28, a little more than twenty-four hours after admission.

Questioning of the parents brought out the fact that the child had never been immunized against diphtheria and that

It was situated in the normal position of the male penis. The anatomic structure was normal except that the urethra was located below the base, that is, hypospadias. The labia were rudimentary, especially the labia minora. The vagina occurred as a horizontal slit but with normal capacity. No testes were found. An attempt was made to determine possible undescended testes but no inguinal canal could be made out.

Fig 4 (case 2)—Appearance at operation after shaving

A virgin speculum was used and a uterine sound introduced to a distance of 3 inches (7.6 cm). The uterus, somewhat smaller than normal, was found in its correct position.

Operative Record—At Memorial Hospital, March 21 1934 under gas-ether anesthesia, a midline incision was made and the abdomen explored. A deviation from the normal was found in the distribution of the colon in that there was no

Fig 5 (case 2)—Showing small opening at base of penis barely sufficient to accommodate urethral os

ascending portion, the ileocecal junction occurring just under the lower border of the liver. The appendix was unusually long and in a state of subacute inflammation, it was removed. The uterus was in its proper location and, while not infantile, was incompletely developed. On the left a large cystic ovary and a normal patent tube were found. There was no right tube or ovary. Attachment of the uterus on this side was by a rudimentary band apparently of the broad ligament. No

testes were present. There was no prostate. The abdomen was closed and an attempt made to improve the vaginal outlet. The penis was amputated, with enough left at the base to provide a possible substitute for the clitoris, and with the idea in mind to protect the urethral canal. The perineum was incised for correction of the horizontal opening of the vagina to the vertical. The vaginal mucous membrane was freed and sutured to the skin.

Recovery from operation was rapid and uneventful. The patient left the hospital on the eighth day, and healing was by primary union. The mons gave a normal appearance. The vagina was practically normal, the only indication of the former state being scars within the vestibule of the vulva, which however did not seem sufficiently contractile to interfere with a capacity for intercourse.

The attitude of the patient was immediately improved. She became optimistic almost over night. At every visit to the office she had some new feature of improvement to report, and at times her enthusiasm led her to exaggeration. However her development has been little less than sensational. She no longer uses depilatories. The beard has practically disappeared,

Fig 6 (case 2)—Present appearance capacity of vagina sufficient for introduction of virgin speculum

and the face is much smoother. The breasts have developed to the size of small lemons and the nipples are prominent. Her voice is less masculine but not yet as satisfactory as desired. She is quite satisfied with her condition, she attends social functions and appears interested in the young men of the neighborhood.

After-Treatment—Within two weeks after the operation, administration of medicines calculated to promote or develop ovarian function was begun. First theelin was given in daily doses for twelve days, then anterior pituitary-like principle from the urine of pregnancy was administered three times a week for two weeks. A rest period of two weeks followed. Theelin in daily doses was again given and on June 11 she began to have cramps, headache and backache. She was nauseated and complained of vertigo. She fainted several times. The medicine was discontinued and an attempt was made to improve her general condition. July 1 treatment was resumed, theelin being given in daily doses. July 11 she had a menstrual showing. The flow was intermittent of bloody character and continued for ten days. It was not normal but definitely menstrual. She will continue to receive six or eight doses of theelin just prior to the expected menstruation for some time and will be kept under observation.

CASE 2—History—D E, aged 9 years of Dusietta, Texas, was given a final diagnosis of pseudohermaphroditism and subacute appendicitis.

There were no symptoms of disease, but the parents presented the patient for determination of predominant sex and for such measures as might seem indicated after exploratory operation. She had been presented to the late Dr. Thompson's

cervical os. There were no testes. The appendix was removed. The penis was amputated, care being taken to preserve urethral integrity and to assist in formation of the vestibule. A plastic operation was done for the establishment of the vulva.

Postoperative Record—There was nothing noteworthy in the postoperative history. Healing was rapid and satisfactory. Care was taken to preserve the vaginal outlet by packing with sterile strips of petrolatum gauze. She has been under observation at regular intervals since the operation and will continue to be until the establishment of the menses, which is confidently expected within a year. Her sisters began menstruation at 10 and she gives promise to be just as early. The vagina is now of normal appearance and the caliber is about what could be expected of a girl of her age. I have introduced a virgin speculum without difficulty and see no reason to anticipate contraction. However, this feature will be looked after in the future. She is now apparently a normal girl, and I have advised that her past sexual anomalies never be discussed with her.

CASE 3—History—M F, aged 24 of Houston, applied for relief from increasingly frequent attacks of painful priapism, sexual upset due to psychophysical disharmony, failure to establish menstruation and apparent bisexuality. The final diagnosis in this case was pseudohermaphroditism and subacute appendicitis.

The patient had had occasional pain in the right lower abdominal quadrant, but not sufficiently severe to cause her to seek relief. There had been the ordinary diseases of childhood. The tonsils had been removed seven years before. There had been no serious diseases or injuries. She had always considered her general health good and she felt strong. She had never menstruated nor had she ever had any of the usual premonitory symptoms of menstrual attempt. During the attacks of priapism the penis became very erect and the condition persisted for several hours. At these times she was tor-

Fig. 7 (case 3)—Appearance of external genitalia

mented at the Medical Department of the Texas State University when she was 9 months old, and it was his announced opinion that she had no vagina. He did some sort of exploration of the external genitalia of the nature of which there is no record and of which the family is uninformed. She was apparently normal in other respects and except for an attack of diphtheria in earlier life had no history of consequence. She was mentally alert, learned easily and was in the fourth grade at school.

The family consisted of the father living and well, the mother living and well, three sisters living and well, and one dead. This child was a hermaphrodite, apparently predominantly female, and died at 3 years of age. She had three cousins who were hermaphrodites, one of them is dead.

Physical Examination—The patient was healthy appearing and of advanced development in most respects she showed the maturity of one at least two years older. She looked decidedly feminine, with well developed mammary glands, rounded hips and legs of good feminine contour. The general physical condition including the lungs, cardiovascular system, kidneys and blood denoted no pathologic condition. The facial expression was that of a girl. There was a penis much larger than is ordinarily found in a boy prior to the age of puberty. It was well formed and apparently of normal anatomic structure except for the urethra which appeared in hypospadias in a very small opening at the base. This opening was barely sufficient to accommodate the urethral os. There was no frank vaginal canal. The pubic hairs showed the usual male distribution and were very profuse. The voice was feminine but showed an inclination to be squeaky and to break, a characteristic often noted in boys just reaching puberty.

Operative Record—At the Methodist Hospital June 13, 1934, under gas-ether anesthesia a midline incision was made and the abdomen explored. The tubes and ovaries were normal. The uterus was imperfectly developed, especially in view of the physical prematurity otherwise. The appendix was elongated and enlarged and in a state of chronic inflammation. The penis was of apparently normal male formation except for the urethra which was situated at the base (hypospadias). There was no evidence of a pre-existent vaginal outlet that had become occluded, nor was there any scar tissue in the perineal area. After deep perineal incision a vagina was found leading to the

Fig. 8 (case 3)—Showing prepuce and glans

tured with extreme sexual desire, without the ability to determine the preferred sex. She had been tempted to seek relief by means of self abuse but stated that she had never yielded. Until her sister, of like abnormality, was operated on, she, according to her statement, had determined to accept her strange lot and make the best of it. She was working as a domestic and endeavoring to occupy her mind with educational reading. She expressed her situation as that of a 'mule' without hope or promise beyond the day's labor. It was her

belief that the male characteristics predominated, especially since the penis appeared to be making increasingly insistent demands for sexual satisfaction. Her hermaphroditic sister and a cousin with a similar affliction had both been recently operated on by me for sex determination and for such changes in sex organs as appeared advisable. She was quite intelligent and there appeared to be no suspicion of perversion.

Fig 9 (case 3)—Vaginal vestibule five weeks after operation

Physical Examination—The patient was well developed, with facial appearance decidedly masculine, but the body formation with some exceptions, was that of a female. The mammary glands were not developed, but the nipples were practically normal in appearance. She had a heavy beard, which she had been accustomed to remove by shaving and the use of tweezers. The distribution of hair was masculine throughout. There was a well formed penis of ordinary adult size, a normal prepuce and glans. There was no urethral portion, the urethra being in the position of hypospadias, that is at the base. The vagina was of normal proportion, but the labia were rudimentary. A hymen stretched across the posterior vaginal outlet. The uterus in normal position, was not of full adult development. The legs, waist, hips and body generally with the exception of the chest, which had the flat masculine formation, were female in contour. The legs and ankles were especially shapely. The physical condition was found good.

Operative Record—The patient was operated on at the Memorial Hospital July 5 1934. Under gas-ether anesthesia a midline incision was made and thorough exploration done. The appendix was in a state of chronic inflammation, elongated and greatly enlarged and was removed. There were two normal ovaries and two tubes which were patent. The uterus was in proper position but not fully developed. There were no testes and no prostate. The abdomen was closed and the penis was amputated.

Postoperative History—There was a rapid and satisfactory recovery, without unusual incident. She left the hospital by ambulance on the fifth day. Healing was by primary union. No treatment was given for induction of the menses since a normal flow was initiated on July 30 just twenty-five days from the time of the operation. It lasted six days and was of good character, free and without pain. There was some

head fulness and backache. The breasts showed considerable development and the facial hairs were fewer. In the belief that the medicines given her sister for promoting menstrual flow had caused the facial hair to leave, she insisted on receiving similar treatment and is now being given amniotin every other day during the two weeks prior to each anticipated menstrual period.

The only incentive for the menstrual function commencing in this case, so far as I know, was amputation of the offending penis and its prompt beginning is something difficult to account for. Whether the normal cycle, with usual periodicity, will be established belongs to the future. It is quite likely that there will be considerable irregularity of appearance, even though the final goal of approximate normality is reached. She is quite a different individual and shows distinct relief from her former repressed embarrassment arising out of psychophysical imbalance.

The patient has recently secured a contract as a teacher in the schools and appears quite contented.

SUMMARY

1 Three cases of hermaphroditism occurred in the same family stem. Two other children, both dead, are supposed to have been endowed with the same or similar sex anomalies, their cases are not reported for lack of authentication by personal examination.

2 All these patients were of a single generation, no others, so far as ascertainable, were in the least degree hermaphroditic in the preceding or succeeding generations. Thirty-six offspring of the brothers and sisters of these hermaphrodites have been checked over and found normal in all respects.

Fig 10 (case 3)—Appearance of vulva five weeks after operation

3 In all the patients of the series, abdominal exploration was done for determination of the dominant sex and this was followed by such plastic operations as appeared advisable in the interest of conformatory relief.

4 In some way, natural forces within an individual seem to be able to correct an embryonic error, once the offense of this error is removed.

EMBOLISM

FOLLOWING INSTRUMENTATION AND INJECTION OF
OIL INTO THE URINARY BLADDERJESSE L. CARR, M.D.
AND
CLARK M. JOHNSON, M.D.
SAN FRANCISCO

It is more than a hundred years since Magendie (1827) found that fluid fat circulating in the blood stream might obstruct a vessel. Perhaps because of the apparent simplicity of this mechanical obstruction he did little experimental work with circulating fat and no large recognition was given to his discovery. In 1865 Virchow injected oil into the neck vein of a dog and produced a fatal fat embolism, which was accompanied by acute pulmonary edema. A few years later Riedel¹ produced extensive fat embolism in the lungs by oil, which had been injected into an artery and which had in the meantime passed through other organs. Scriba² demonstrated that droplets of fat could pass through other organs and the lungs as well, without difficulty in certain instances, previously a patent foramen ovale had been considered essential to the passage of embolic fat from the lesser to the greater circulation. Scriba also noted, in continuing his experiment, that a large amount of oil could be injected into the circulation without fatal effect, and he computed that as high as one third of the body fat mass could be injected at one sitting without fatal results. Ribbert³ estimated in 1894 that the fatal human oil dosage was between 30 and 40 cc when injected intravenously, but Landois,⁴ basing his computation on Scriba's ratio, put the figure at 210 cc. In an actual proof, Fibiger⁵ reported the death of a young adult male after the accidental injection of oil into the vein. Fuchsig⁶ reported the fatal intravenous oil dosage at 2 Gm per kilogram, and Wegelin,⁷ after reference to the contention of Merckel that intravenous oil injection in dogs testified to no conclusion as to human embolism, reported the work of Kojo on the relative effects of various oils. In quoting Kojo, he stated that in rabbits an injection of from 0.6 to 0.7 cc of olive oil per kilogram was well borne, whereas from 1 to 1.5 cc per kilogram caused death. In any event, and in spite of the apparent disagreement as to the amount of oil necessary to cause death, it is apparent that oil in somewhat varying amounts injected into the venous circulation will cause death by fat embolism. Lehman and Moore,⁸ attempting to settle this controversy, injected varying doses of cottonseed oil into twelve dogs. Three dogs had received 2 cc of oil per kilogram and died spontaneously within a few hours. Two other animals receiving 1.7 and 1.66 cc per kilogram, respectively, died within a few days. Six dogs, which were injected with 1.5 cc per kilogram or less, survived. Killed later for autopsy, they showed

no typical pathologic changes. Lehman and Moore draw the amazing comparison that, if the human being can be compared with the dog, the average sized human being can tolerate an injection of 120 cc. On the other hand, fat embolism may occur with but little or no introduction of fat into the venous system. Carrara⁹ reported fat embolism present at necropsy in 22 per cent of deaths from cardiovascular-renal disease and in 44 per cent of burns. Catsaras¹⁰ found fat emboli in the lungs in eighteen of sixty-seven cases of postinfluenza pneumonia. Fat embolism has been reported in acidosis,¹¹ potassium chlorate poisoning,¹² carbon monoxide poisoning,⁹ profound sepsis,¹³ chronic alcoholism,¹³ chloroform narcosis,¹¹ diabetic retinitis,¹⁴ phlegmonous gastritis,¹³ acute pancreatitis,⁹ chronic tuberculosis,⁹ hepatitis, suppression of the menses, splenitis, carcinomatosis and sarcomatosis (the last five from the literature by Warthin¹⁵), while Lehman and

Fig 1—Basilar artery with thrombosis

Moore have produced fat embolism without trauma in dogs by ether administration, either by vein or by inhalation.

It becomes apparent then that, while large amounts of fat injected intravenously may cause fat embolism, the same condition may ensue following the intravenous injection of small amounts of fat or from physiopathologic changes in the plasma, entirely independent of any outside fat source.

The injection of oil into the urethra has been found to facilitate the passage of sounds or catheters into the bladder, especially in patients with urethral stricture. Thompson¹⁶ pioneered with such a method nearly seventy years ago, while Cabot, Crane and many other urologists have recently adopted this procedure. Thompson, after many years of observation, remarked

From the Departments of Pathology and Urology of the University of California Medical School, the San Francisco City and County Hospital and the San Francisco Coroner's Office.

on the ease with which bacteria, various drugs, air and semisolids, such as oil, might pass from the urethra into the circulation, and he indicated that this danger was greatly accentuated after the urethral mucosa had been traumatized. Schönfeld and Muller,¹⁷ Scott¹⁸ and others, both clinically and experimentally, have substantiated this opinion, while Jeck¹⁹ and Mathe²⁰ are among those who have reported fatal cases of air embolism following pneumatic dilation of the bladder. The passage of bacteria into the blood stream by way of the urethral mucosa is commonly manifest by the so-called urethral chill, and Patterson²¹ has recently reported two fatal cases of oil embolism following urethral instrumentation facilitated by the use of oil.

REPORT OF CASE

The following is the report of still another case of fatal oil embolism, which was treated at the San Francisco City and County Hospital, with autopsy at the San Francisco coroner's office.

History—A man, aged 34 who entered the hospital, had had previous gonorrheal infection followed by stricture of the urethra and for some time the urinary stream had been slow and small. One week previous to entry there had been a complete retention relieved by catheterization, which was difficult. On entry he had not voided at all for at least eight hours. The bladder could be felt extending up to the umbilicus. Attempts were made by one of the house staff to pass soft rubber catheters of various sizes without success. A metal stilet was then used to guide the catheter also without success. There was some bleeding from the urethra. About 50 cc of sterile cottonseed oil was then gently injected into the urethra, some of which passed on into the bladder. The patient then voided several hundred cubic centimeters of urine and complained of

Fig 2—Cerebral vessels showing thrombosis and peripheral oil droplets

feeling dizzy. The bladder was still palpable but the patient was put to bed as he felt relieved. One hour later he became pale and then cyanotic, his respirations became deep and stertorous, and he could not be roused. There were no chills or convulsions. He died four hours later.

Pathologic Report—A survey of the body grossly showed a young white man of normal external appearance, the body without distinguishing marks or deformities. The usual incision was made. The abdominal tissues were in their normal relationships and were normal in every respect on gross examination. When the thoracic cage was lifted off, the heart was in diastole and filled with clotted blood but was normal in size, shape and position and the pericardial cavity was empty.

Fig 3—Oil droplets in pulmonary capillaries

The lungs were aerated and showed no areas of infarction, infection, fibrosis or other pathologic change. Examination of the bladder showed a moderate injection of the mucosa and a few tears in the mucosa of the posterior urethra. These were not large, however, and there was no active bleeding from them. The stricture that was the cause of the patient's entry into the hospital had been broken and dilated by instrumentation. There were about 400 cc of clear yellow urine and 20 cc of oil in the bladder. When the cranial cap was lifted off, a rather wet brain was seen which weighed 1550 Gm. The convolutions and sulci were normal and the leptomeninges showed no pathologic changes. In the basilar artery there was a blood clot occluding the lumen which apparently had formed there before death (fig 1). It was felt that this clot might have been associated with the sudden death of the patient and it was somewhat discolored, being browner and of a darker color than a normal blood clot. No other pathologic changes were seen. Sections were taken of all the organs.

Microscopic sections of the brain showed no cortical changes and no areas of degeneration, infection or infarction. Sections of the vessels of the base, however, showed a general occlusion with premortem clots and about the borders of the clots occluding the lumens were small vacuoles which stained a deep pink with sudan III (fig 2). They also reduced osmium peroxide, giving a deep black with this stain. Many of the vessels throughout the cortex were occluded by such a mechanism, and when small sections of the brain were immersed in sudan III, small punctate red dots developed diffusely throughout the cortical structure.

The heart muscle was normal, the myofibrils being well preserved. The endocardium and pericardium were normal and the coronary vessels were free from clots and foreign material. Sections of the lung showed a normal aeration with the alveolar spaces distended. In some places, however, the bronchioles were filled with pus, and in the alveolar spaces adjacent to these there was a purulent exudate filling them as well. Throughout the capillaries in the alveolar walls more vacuoles could be seen and these gave a vivid reaction when stained for fat (fig 3). The liver showed a normal structure with well preserved cells, normal portal arrangements, and sinusoids.

free of oil or abnormal content. The spleen had a normal capsule, trabeculations and pulp. The sinusoids were somewhat distended by erythrocytes, but there was no increase in fibrosis in the splenic structure. No oil or other foreign material could be found. The pancreas showed normal acinous cords, patent ducts, lined with intact epithelium, a normal vascular system and normal islets. The adrenals showed the normal cortical zones with ample lipid in the fascicular layer and a normal medullary region on either side. There was no oil in the adrenal circulation. In the kidneys, however, the glomerular tufts were distended and engorged with blood, and throughout droplets giving a positive stain for fat were found in the capillary channels of the glomerular tufts (figs 4 and 5). They were not seen in the renal circulation elsewhere, however, and the glomerular capsules, renal tubules and pelvic membranes were essentially normal. The ureters were normal. There was a moderate injection of the mucosa of the bladder but no infection was evident and there was no exudate on the mucosa or beneath it. Sections taken down in the area of traumatization showed destruction of the continuity of the mucosa with a few leukocytes scattered about and some increase in fibrous tissue directly beneath the mucosa. No oil, however, was found in the vascular channels here. Sections of the prostate showed a normal gland and the testicles were in active spermatogenesis and demonstrated the usual interstitial cells. Sections of the gastro-intestinal tract were normal throughout.

As bodies staining with sudan III and osmic acid were found occluding capillaries in the kidneys, lungs and brain, a diagnosis of oil embolism with death was made and it was presumed that the oil so entering the circulation was from the posterior urethra.

COMMENT

In spite of the fact that here is a direct chain of circumstance proceeding from the instrumentation and

abnormal circumstances may not be the fat which causes the embolism. They suggest rather that such fat introduced artificially must in some way associate pathologically with the free neutral fat in the blood stream, which is there physiologically. In this case there is no indication that the fat metabolism was upset or that the emboli seen in the various organs described are

Fig 5—Oil droplets in a glomerular tuft

composed of other fat than that which was accidentally injected, although, of course, it was not possible to analyze these droplets for determination of their specific formulas.

CONCLUSIONS

1. Widely varying amounts of oil or fat may cause death by fat embolism.
2. The posterior urethra is an active absorptive bed and can be the portal of entry of sufficient fat or oil to cause fatal embolism.
3. The danger of oil absorption with embolism is greatly increased by previous urethral instrumentation.
4. Nothing should be injected into the traumatized posterior urethra that cannot be safely injected intravenously.

Fig 4—Oil droplets in glomerular capillaries.

oil injection through rather suggestive symptoms to the death of an individual, we are still at a loss to explain why a small amount of oil entering the blood stream in this way should cause death when it is known that larger amounts can be injected intravenously without causing definite symptoms. As Lehman and Moore⁸ suggest, the entrance of fat into the blood stream cannot be definitely regarded as disease producing in a direct way, and they indicate that this fat entering in

The Aqueduct of Sylvius—The aqueduct of Sylvius is a narrow midline canal connecting the third and fourth ventricles. It is about 15 Gm in length and varies in width from 1 to 2 mm. The diameter is not quite uniform, being slightly narrower at the rostral end due to the ventral projection of the posterior commissure, and wider in the midportion (ventriculus mesencephali of Retzius). In its rostral half the aqueduct courses almost horizontally but at about its midportion it curves sharply, becoming almost vertical. The aqueduct has an arched roof consisting of the quadrigeminal plate and posterior commissure, and a floor formed by the tegmentum of the midbrain and the subependymal gray matter peripheral to which the cerebral peduncles lie—Davidoff, L. M., and Dyke, C. G. The Demonstration of Normal Cerebral Structures by Means of Encephalography. V. The Ventricles, Interventricular Foramina, and Aqueduct of Sylvius, *Bull Neurol Inst New York* 4:91 (March) 1935.

SWEAT REDUCING SUBSTANCES IN
YEAST DERMATOSESTHEODORE CORNBLEET, M D
CHICAGO

For a long time it has been suspected that yeast infections of the skin are associated with some error in carbohydrate metabolism. The condition is most prevalent among Jews, a people who are prone to difficulties in sugar metabolism. Moreover, yeasts require a ready supply of sugar to thrive. In addition, yeast infections are fairly common in diabetic patients and in the genital tract of diabetic women. In spite of this evidence no carbohydrate metabolic error has been definitely linked with the majority of cases of moniliasis. Examination of the blood of most of the affected subjects has not

Fig. 1—Erosio interdigitalis saccharomycosis and yeast paronychia in the same individual

shown it to have any deviations from the normal. Since it would indeed be surprising if any carbohydrate metabolic change should be present without showing itself in the blood, and none has been regularly found there, investigators have been discouraged from looking elsewhere.

There are several reasons, however, for suspecting that the sweat may be the seat of a carbohydrate metabolic error. First, yeast infections are surface manifestations and generally remain such. Second, they are mostly confined to folds in which sweat stagnates. Third, it is possible to have a concentration of a sweat ingredient (reducing substance) out of all proportion to that found in the blood. Thus, I have recently found potassium relatively more concentrated in the sweat than in the blood.

I have been making a general survey of the constituent properties of sweat and in this I have included observations on its reducing powers, which I shall hereafter refer to in equivalents of dextrose. Twelve persons without any yeast infections were selected at random and sweated in a heat chamber. They served as controls to patients with yeast infections. Six persons with yeast paronychia, four adults with perleche, eight with erosio interdigitalis saccharomycetica and three with yeast infections under the breasts, in the groins and around the umbilicus constituted the pathologic group. The sweat was collected by placing the patient in a rubber sack, closely drawn up around him as far as the neck, and sweated in a heat chamber that uses electric light bulbs as the source of heat. The temperature varied from 110 to 130 F. He remained in the heat chamber for thirty minutes. Blood was withdrawn for sugar determination just before and after sweating.

In all cases, pathologic as well as normal, the blood sugar rose during sweating. This rise ranged from 5 to 30 mg per hundred cubic centimeters. The extreme rises occurred in one of the two diabetic patients in the series. In general, those in the pathologic group tended to have the greater rise in blood sugar levels during the sweating as compared to the control group. Sweat reducing substance of the control group varied between equivalents of 20 and 40 mg of dextrose per hundred cubic centimeters. This agrees fairly well with the values found by Silvers, Forster and Talbert,¹ who found from 28 to 40 mg per hundred cubic centimeters. Usher and Rabinowitch² obtained somewhat lower concentrations, but their figures cannot be directly compared with mine since their procedure was somewhat different. Whereas I gave no fluids, they gave 250 cc of water one-half hour before and a like amount one-half hour after the sweating experiment was started which lasted an hour. Moreover, they used pilocarpine, whereas I did not.

The sweat from the pathologic group contained from 55 to 90 mg per hundred cubic centimeters. Even the lowest values in the group were distinctly higher than the highest ones for the controls. All the values for these normal and pathologic groups were obtained while the subjects were fasting. The Folin-Wu method for sugar estimation was used throughout.

The normal group secreted from 25 to 300 cc in a half hour by my method, whereas the pathologic group secreted from 5 to 60 cc under the same conditions. It might appear that the reason for the higher concentration of reducing substance in the sweat of the pathologic group is that it sweated so much less than the controls. It is plausible that the larger amount of fluid secreted would dilute the reducing substance present. This, however, is not true. I found that by collecting sweat in a series of batches from a person during one sitting that successive samples did not vary much in their reducing substance concentrations. In fact, in some persons I found an actual increase to take place, at least for the time of the experiment, one-half hour. Thus, one man secreted 10 cc of sweat in the first ten minutes and the reducing substance of this was 26 mg per hundred cubic centimeters. In the next twenty minutes he secreted 156 cc, the reducing substance con-

¹ Silvers S, Forster W and Talbert G A. Simultaneous Study of the Constituents of the Sweat Urine and Blood. VI. Sugar. *Am J Physiol* 84: 577 (April) 1928.
² Usher Barney, and Rabinowitch I M. Excretion of Sugar in Sweat. Its Relationship to Eczema, Arch. Dermat. & Syph 10: 706 (Dec) 1927.

centration of which was 32 mg. In general, however successive samples did not decrease much in reducing substance concentration as more sweat was secreted.

The question now comes up as to whether the reducing substance of the sweat is actually sugar. Usher and Rabinowitch² by fermentation experiments came to the conclusion that all of the reducing substance was fermentable and consequently probably sugar. Using their technic, I can corroborate their results. Moreover, lactic acid, which is an intermediary metabolite of sugar, is found in great abundance in sweat.

In phenylhydrazine tests³ on sweat I have been unsuccessful in demonstrating osazones. None of the normal control subjects yielded osazones. The Molisch test on these specimens was negative. From the standpoint of the phenylhydrazine test, I consider it as yet indeterminate whether all the reducing substance, or part of it, is actually sugar.

If these reducing substances in sweat are indeed sugar, does that help to explain the yeast infections in these patients? A simple increase in sweat content will allow a heavier growth of yeast, and this could determine the successful invasion of the skin. It has been definitely shown that the size of an inoculum of microorganisms is a decisive factor for success of a transplant of a culture. An increase in the number of yeasts might not, however, be the only factor. The increased sugar could conceivably change the epithelium physically. I therefore immersed horn cells in watery mediums that contained graduated quantities of sugar but could detect no difference in the softening or clearing powers of the different concentrations of sugar.

In most of the persons in the pathologic group there was decreased sweating, so that the idea of maceration from excessive sweat with them may be dismissed. Nor for any other reason by itself does the amount of sweat explain the infections. Those of my tested subjects who sweated little and had normal concentrations of reducing substances did not have yeast infections.

The difference between the normal and pathologic groups in the concentration of their sweat is not adequately reflected in the figures for freshly secreted sweat. The difference in concentration between the two groups becomes increasingly exaggerated as the sweat is evaporated. Since it is the evaporated residue that is present for yeast consumption on the skin, it is the exaggerated difference that really comes to be the significant one. It becomes evident then that, the greater the concentration of the reducing substance in freshly secreted sweat, the more this piles up in the evaporated end product. A small difference in concentration to begin with becomes a much larger one when the sweat is partially evaporated and presented for consumption to the yeast. Thus to take two examples, one from a normal control, the other from a patient with moniliasis. Ten cubic centimeters of sweat collected from each was evaporated to 3 cc in a large flat plate at a temperature that varied between 36 and 40 C. The dishes were placed on hot plates with enough layers of asbestos between to regulate the temperature within these limits. The reducing substance in the normal sweat was equivalent to 20 mg of dextrose per hundred cubic centimeters and in that of the pathologic 73 mg. The difference between the two was 53 mg. After partial evaporation, the normal sample contained reducing substances equivalent to 42.1 mg of dextrose, while the

pathologic one contained 128 mg. The difference after evaporation was about 86 mg or an increased difference of 33 mg as compared to that before evaporation.

Usher and Rabinowitch² reduce the sweat sugar excretions to values for the amount of sugar per hour or unit of time. This gives useful and instructive data. It is doubtful, however, as to whether such figures carry any final significance for present considerations. During a given period most of the patients with yeast infections excreted less total reducing substance than did the normals. Their sweat, however, was much more concentrated in respect to reducing substance. The increase per unit of volume did not make up for the meager amounts of total fluid they secreted. Since it was they who had the yeast infections, it would seem that not the total amount of reducing substance

Fig. 2.—*Erosio interdigitalis saccharomycosis* and *perlèche* in the same individual. This woman also had a submammary dermatitis.

excreted but rather its concentration in the sweat was decisive for yeast infection.

That a reducing substance residue does definitely remain on the surface of the skin all the time seems to be shown by the fact that a sample collected from a person after bathing contains less reducing substance than one collected without previous bathing. In a man whose sweat contained from 40 to 44 mg per hundred cubic centimeters on three occasions in eight days, a shower bath before the collection of the sweat reduced the concentration to 25 mg per hundred cubic centimeters. Thus apparently some of the reducing substance clinging to the surface of the skin, which would have given his sweat a concentration of from 40 to 44 mg per hundred cubic centimeters, was washed off in bathing. This result is representative of three other persons examined. Since the reducing substance

3 With the technical assistance of Dr. Morris A. Kaplan.

concentrations that I reported for the normal and pathologic groups were obtained by sweating without previous bathing, it would mean that these figures would have to be scaled down 40 per cent in order to obtain the true concentration of reducing substance of freshly secreted sweat

Could volatile substances account for any of the reducing substances found in sweat? To answer this, 100 cc of sweat was distilled slowly in such a way that the distillate was collected under a small amount of water. This water was tested for reducing substances and was found to contain none. The original 100 cc contained 47 mg, and when the 100 cc was distilled to a residue of 22.5 cc this contained 109 mg per hundred cubic centimeters. This experiment seems to show that none of the reducing power of sweat can be accounted for by volatile substances.

If the high reducing substance content of the sweat is the fundamental cause of yeast infections it would appear that one rational method of combating them is to reduce the sugar concentration. In attempts at this I made observations on the effect of the sweat reducing substance concentration from the administration of several drugs and biologic substances. These included insulin, pilocarpine, atropine, solution of pituitary, amniotin, epinephrine, and dextrose itself. The results of these procedures showed that, in general, quantitative deviation in blood sugar content will reflect itself in the same direction in the sweat reducing substance but that the changes in the latter were much smaller. Thus with 10 units of insulin, given after the first sample of blood was taken one diabetic patient had her blood sugar reduced from 170 to 158 mg per hundred cubic centimeters while sweating, and the sweat contained 57 mg equivalents. Without insulin, the blood went from 167 to 182 mg during sweating, while the sweat was 65 mg. Epinephrine produced increases in the sweat reducing substance but also with more substantial ones in the blood. It induced greater changes in those with much sweat reducing substance. Between these extremes there were values found from the use of pilocarpine, solution of pituitary, atropine and amniotin. The administration of sugar by mouth has a definite effect on the content of sweat reducing substance. The group with yeast infections showed a somewhat greater change in the content of sweat reducing substance after the ingestion of 50 Gm of dextrose as compared with the control group. The general method in these procedures for influencing the blood sugar and sweat reducing substance was to take blood samples, administer the drug, biologic product or sugar, wait fifteen minutes and then sweat the patient. A blood sample was then again withdrawn directly after the patient sweated for half an hour.

Another mechanism must undoubtedly be at work to abet the yeast infections under wet dressings and in those in a continuous water bath. Here it is evident that any sugar on the skin surface would be quickly dissolved away and its concentration decreased. I⁴ have already shown that moist skin areas are not as efficient as drier ones in ridding themselves of micro-organisms. Every one is familiar with the difficulty of growing a culture on otherwise suitable mediums that have dried out. The epidermis that has become soggy by the continuous presence of moisture allows the

organisms to gain a foothold by not being able to inhibit them from the start. They are further encouraged by their ease in penetrating a softened cell. The fact that the sugar concentration is reduced will not in itself prevent yeast growth. In the case of the water bath, the decrease in concentration of sugar is more than counteracted by the ease with which the yeast gains a foothold on and invades the wet epidermis.

In the case of the contact areas of the skin—the submammary folds, the interdigital spaces and the corners of the mouth—not only is moisture conducive toward gaining a foothold in the epidermis but larger amounts of reducing substance are at their disposal. I have previously found⁵ that the nail fold, just as the skin contact areas, is also deficient in inactivating micro-organisms. It presents the same conditions for the growth of yeast as do the other areas that are more obviously moist.

In practically all forms of yeast infection of contact areas, it is *Monilia albicans* that is found. Benham and Hopkins⁶ could not isolate this organism from normal skins and concluded that when one finds this organism in a lesion of the skin one is dealing with one of a group of dermatoses that may be referred to as moniliasis. The numbers of this group seem to be closely related, if not in fact identical. In my series of patients a goodly number had multiple manifestations at the same time.

In three of them there was perleche, paronychia, and erosio interdigitalis simultaneously. The site affected varies the morphology of the lesion, and this is known clinically under a distinctive name. It is simpler to look on such occurrences as clinical variants of the same kind of yeast or monilial infection. In that way one is better prepared for the same background for all, a similar environment for a single causal organism. This environment would seem from my experiments to be a ready supply of sugar furnished by unevaporated sweat and epithelial cells that are laden with moisture.

Since the organisms that cause eczematoid ringworm thrive best with a ready supply of sugar, and they too confine their original activities in interdigital spaces, it is to be presumed that a factor of reducing substance concentration in sweat might determine infection with them. This possibility I have recently begun to investigate.

SUMMARY

Persons with yeast dermatoses have higher concentrations of reducing substances in their sweat as compared to normals. This reducing agent seems to be sugar as shown by fermentation tests and observations on sweat lactic acid, an intermediary metabolite of sugar. Preliminary phenylhydrazine tests, however, have not so far positively confirmed the presence of sugar. None of the reducing substance in sweat can be accounted for by volatile substances. The reducing substance in sweat remains relatively constant if there is no evaporation. Contact areas or skin folds retard evaporation of sweat and thus make available more reducing substance and moisture for micro-organisms. It is these areas which are deficient, too, in their powers for sterilizing themselves. Organisms are then able to get a foothold, and if they are yeasts they are particu-

larly able to thrive in the available stagnating sweat medium rich in reducing substance supplies. It is common to find one person with several types of yeast infection. It is convenient, and I think correct, to look on these various types of clinical entities as being merely morphologic differences produced by the accident of site affected. They are all due to *Monilia albicans* on a background of high concentration of sweat reducing substance. Eczematoid ringworm probably is produced by the same background but by different organisms. Attempts to lower the concentration of sweat reducing substance by influencing the blood sugar level were not encouraging. Sugar ingestion does make some difference, and this is greater in persons with high concentration of sweat reducing substance. It seems an advisable measure, although one of limited value, to reduce the carbohydrate intake of persons with moniliasis.

SUTURE OF STAB WOUND OF THE HEART

REPORT OF CASE

GEORGE BENET, M.D.

AND

CHARLES GORDON SPIVEY, M.D.
COLUMBIA, S. C.

Until the end of the nineteenth century, thoracic surgery lagged far behind the advances made in abdominal surgery, and any surgical procedure on the heart itself was considered an impossibility. As late as 1883 the great Billroth announced that "the surgeon who should attempt to suture a wound of the heart would lose the respect of his colleagues." It remained for the intrepid Cappelán to venture into this unknown field. The first recorded attempt to suture a stab wound of the heart was made by Cappelán in 1895. His patient died after two days. Farina made the second attempt in 1896, with fatal results. The first successful case was that of Rehn in 1897, and ten years later he was able to collect 124 cases in which suture had been performed, with a 40 per cent recovery. In 1920 the literature contained 305 cases, with 50.4 per cent recovery (Tuffier), and Smith assembled fifty-eight cases between 1912 and 1923, with 66⅓ per cent recovery. In the light of present-day knowledge, this increasing percentage of recoveries will doubtless continue. The brilliant work of Cutler and Beck¹ during the past decade has gone far to place cardiac surgery on a firm footing. Cutler's successful section of a stenosed mitral valve marks an epoch in this field of endeavor and is one of the great triumphs of modern surgery.

Certain factors are essential to success in cardiac suture. Among the more important may be included the element of elapsed time after the wound is received, the size and character of the wound in the heart muscle, the incidence of other extracardiac injuries, the age of the patient and the general cardiac condition. One

great danger to be avoided by the surgeon is the natural tendency to haste. A careful dissection in the early stages of the operation, with particular reference to avoiding perforation of the pleura, will obviate complications that are severe and may well prove fatal. The diagnosis is not always simple and depends on a stab wound over the cardiac area with little or no external bleeding, feeble or absent radial pulse, low blood pressure, and the important physical signs associated with "heart tamponade", i. e., engorged vessels of the neck and muffled heart sounds. With the increase of pressure within the pericardium there may be respiratory embarrassment. The general picture is that of extensive hemorrhage, which, coupled with the physical changes outlined, justifies the diagnosis. The differential diagnosis should include injury to the lung, intercostal artery, mammary artery, pericardial wall, and penetrating as opposed to perforating, wounds of the heart. However, a severed coronary artery may give rise to heart tamponade, in the absence of a perforation of the endocardium.

The choice of surgical approach to the heart lies between the midsternal incision employed by Cutler² in his operation for valvular disease and the parasternal. The latter is simpler and more rapidly performed. Median sternotomy is a formidable undertaking and probably not well tolerated by an exsanguinated patient. The parasternal incision gives an excellent exposure of the left ventricle, and by transverse section of the sternum, with forward dislocation, the right ventricle is brought into the field of operation. With the pericardium opened and the tamponade relieved, the heart rapidly regains its forceful contractions and the surgeon finds himself operating in a mass of bloody foam, which is not conducive to equanimity. In handling the

Fig 1—Blood pressure and respiration rate.

heart, strangulation of the base must be guarded against, a feat difficult to accomplish in the excitement of the moment.

The heart can be handled most gently by means of one or two deep sutures placed in the apical region of the left ventricle. By traction upon these threads one can elevate the heart from its bed rotate it and expose all portions to view. Success seems to depend upon the avoidance of obstruction to the flow of blood in the heart. This method of using traction sutures instead of grasping the organ forcibly in the hand seems to result in almost no interference with either the flow of blood in the coronary vessels or in the heart itself.^{1a}

2 Cutler E. C. The Present Status of Cardiac Surgery. Surg. Gynec. & Obst. 54: 274-279 (Feb.) 1932. Cutler E. C. Cardiac Surgery. J. Maine M. A. 23: 156-161 (Aug.) 1932.

1 (a) Cutler E. C. and Beck C. S. Surgery of the Heart and Pericardium. Nelson's Surgery, vol. 4, pp. 233-386. (b) Cutler E. C. and Beck C. S. The Technique of Cardiography. Surg. Gynec. & Obst. 45: 74-79 (July) 1927. (c) The Present Status of the Surgical Procedures in Chronic Valvular Disease of the Heart. Arch. Surg. 18: 403-416 (Jan. pt. 1) 1929.

With the wound in the cardiac wall localized, the hemorrhage can be controlled by a finger tip, and suture performed. A double suture has been advocated as a means of plugging the needle hole and avoiding troublesome oozing. It is well to remember that, in closing the pericardium, the lower extremity of the wound should be left open for a distance of at least 3 cm to permit drainage. It is generally agreed that a drain should not be placed within the pericardial sac. In this connection, the experimental work of Beck³ is illuminat-

Fig. 2—Electrocardiographic record made twelve hours following operation showing a rate of 111 regular and PR 0.16 second. No abnormality was noted other than tachycardia and evidence of left axis deviation.

ing. He found that adhesions between the heart and the pericardium were readily produced by merely rubbing the pericardial surface with surgical gauze. Should the pleura be opened by accident, and collapse of the lung ensue, aspiration of air from the thoracic cavity should be carried out immediately after closing the chest wall. It has been suggested that gas-oxygen-ether be administered as an anesthetic in these cases, with a pressure only slightly greater than atmospheric, to guard against collapse of the lung in the event that the pleura is opened.

The postoperative care of these cases is all important, and especially so if a pneumothorax exists. Should the patient survive forty-eight hours in the presence of a pneumothorax, it rapidly resolves itself into a pulmonary rather than a cardiac condition. Pleural effusion is almost inevitable and requires repeated aspiration and, eventually, rib resection if suppuration develops. In this pulmonary complication the use of an oxygen tent will prove of great value in reducing the high respiratory rate and preventing exhaustion. A serious complication following cardiac suture is cerebral delirium, which may take a violent form. This is doubtless due to the prolonged cerebral anemia induced by extensive hemorrhage and low blood pressure. This can be combated only by large doses of morphine, continued for days. This drug is an essential aid in the after-care of cardiac suture when there has been extensive loss of blood. Probably the most serious complication of this condition is suppurative pericarditis, and its incidence is not to be wondered at when one considers the passage of a dirty knife through the pericardium. However, this is not the only possible infective agent. Several cases have been reported in the literature in which this complication existed when the operation was hastily performed, with improper sterili-

zation of instruments. Certainly, this is another argument against haste, and it should be needless to remark that the most rigid aseptic technic is imperative.

REPORT OF CASE

History—C. T., a Negro youth, aged 16, an inmate of the South Carolina State Reformatory for Negro Boys, was stabbed by a fellow prisoner, June 27, 1934, at 8:30 p. m. The knife entered the anterior chest wall. He was immediately taken to the Columbia Hospital by Dr. C. G. Spivey, the reformatory physician.

He was conscious but in profound shock. There was no external bleeding from the chest wound. This wound, approximately 3 cm in length, was in the right fourth intercostal space, at the sternal margin. The temperature was 96 F. The radial pulse was absent and the blood pressure was too low to record. The breath sounds in both lungs were clear and distinct, and no dulness was demonstrable in either base. The heart sounds were audible, but muffled and indistinct throughout the precordia, the rate was 90 to the minute. Red blood cells numbered 3,120,000, leukocytes, 10,000, hemoglobin was 55 per cent. The urine was normal. (From the reformatory records it was learned that his normal blood pressure was 110 systolic, 70 diastolic. The Wassermann reaction was negative.) He was given two one-fourth gram doses of morphine, half an hour apart, and treated for shock. An hour and a half following the injury the radial pulse was fairly palpable and the skin seemed less cold. The blood pressure was 28 systolic, 20 diastolic. A diagnosis of stab wound of the heart was made, but operation was further delayed owing to the slight degree of improvement and the hope that he would further improve. At 11 o'clock, or two hours and a half after the wound was received the general condition had definitely improved, with a fairly good pulse at the wrist, and a blood pressure of 48 systolic, 28 diastolic. It was decided that operation could be attempted. He was given no fluids.

Operation—Under a light ether anesthesia with open mask a left parasternal incision was made, exposing the fifth, sixth and seventh ribs. The cartilages of these ribs were cut close

Fig. 3—Condition on the thirteenth day following operation showing left pleural effusion and displacement of the heart.

to the sternum and the bony portions of the ribs partially divided with a costotome, just beyond the cartilaginous attachments. In lifting this hinged rib flap, the pleura was accidentally torn beyond repair, resulting in an immediate massive collapse of the left lung. There was marked respiratory embarrassment, and for a few moments it was believed that this would terminate fatally. However this unfortunate accident gave an excellent exposure of the pericardium which was seen as a distended round bluish mass. The peri-

cardial wall was opened, and several handfuls of blood clot were actually forced out of the sac by the contractions of the heart. With this relief of the tamponade the contractions of the heart rapidly increased in force and filled the pericardium with a swirling mass of blood and foam which added little to our exposure. It was soon apparent that the wound was not in the left ventricle, as the rush of blood appeared from between the sternum and the violently beating heart. With a costotome, the sternum was divided transversely and dislocated forward. This gave a fairly good view of the right ventricle and for the

³ Beck, C. S. The Surgical Treatment of Pericardial Scar. J. A. M. A. 97: 824-830 (Sept. 19) 1931. Beck, C. S. and Isaac, L. Pericardiac Tamponade. J. Thoracic Surg. 1: 124 (Dec.) 1931. Beck, C. S. Wounds of the Heart. Arch. Surg. 13: 205 (Aug.) 1926.

first time a column of blood was seen about the size of a match stick squirting from the anterior wall of the right ventricle. This was controlled by a finger tip. There was apparently no injury to the coronary artery or to its interventricular branch. With some difficulty, owing to the rapid movements of the organ, a single strand of chromic catgut suture was introduced beneath the finger placed on the wound and tied. This sufficed to control the hemorrhage. Whether or not the needle passed into the endocardium, we are unable to say. At this time the heart was beating regularly and forcefully although it had reacted

Fig 4—Patient six weeks following operation, showing original stab wound and beginning keloid in operative scar

immediately to any strangulation of the base in handling. The respirations were rapid but the general condition was surprisingly good. The incision in the pericardium was closed with a loose continuous catgut suture. The pericardial sac was not drained, and an opening was not left at the lower extremity of the wound. The wound in the chest wall was closed by replacing the hinged rib flap.

At the end of the operation the pulse was 120 forceful and regular. The blood pressure was 145 systolic, 90 diastolic. Respirations were 40. Five hundred cubic centimeters of 5 per cent dextrose was slowly introduced intravenously with a small needle. Within six hours the blood pressure dropped to 98/68 and within a week stabilized at 110/70. During the following week the convalescence was stormy with violent cerebral delirium which was controlled only by massive doses of morphine.

An oxygen tent was employed during this period, with a marked reduction in the respiratory rate. During the second week a pleural effusion developed on the affected side and was aspirated daily until suppuration required a rib resection during the fourth week. From the time of the second operation the convalescence was uneventful. Before the patient's discharge from the hospital in the seventh week he was examined by Dr O Benedict Mayer who reported no cardiac embarrassment and no clinical signs suggesting the presence of pericardial adhesions. Normal mobility of the heart was noted on fluoroscopic examination.

Since discharge from the hospital the boy has returned to his work in the reformatory infirmary.

Medical Building

BURNS, PRODUCED BY RADIO SHORT WAVE AND ULTRA-SHORT WAVE THERAPY

AND THEIR PREVENTION

DAVID H KLING M.D.

WITH A CASE REPORT OF A SEVERE BURN BY
GEORGE O BERG, M.D.

LOS ANGELES

Radio short wave and ultra-short wave apparatus is now extensively advertised and has begun to replace diathermy. At the high frequencies generated by these machines, ranging from ten to a hundred million oscillations per second (equal to wavelengths of from 3 to 30 meters), it is not necessary to apply the current directly to the body through metal electrodes as in diathermy. It is sufficient to place the part to be treated in the electrical field between insulated plates. Heat is generated chiefly by displacement currents within the tissues, which act as a dielectric.

This mode of application conveys the impression that the danger of burns is eliminated. The simplicity and safety of short wave therapy is played up in the sales campaign. Nothing is more erroneous. Burns have been observed clinically and they have been produced experimentally.

This report warns of the great danger ahead and, it is hoped, will bring about the prevention of serious damage.

REPORT OF CASES

Abstracts of the histories of six cases in which burns developed in the course of radio short wave and ultra-short wave therapy are given. The first two cases are from my own material. The third case I was called in to see, this patient received treatment by a salesman

Fig 1 (case 2)—Second degree burn. Blister over the metacarpophalangeal joint of the thumb after twenty four hours

of short wave apparatus. These three cases were second degree burns, of small area, which healed within a few weeks. Cases 4 and 5 were reported to me. Case 6 was observed and is reported by Dr G O Berg. These three cases were third degree burns, with extensive destruction eventually necessitating skin grafts.

CASE 1—A girl, aged 11 years, was treated for fungous infection of the nail bed of the fourth right finger with a 6 meter, ultra-short wave machine of 225 watt output. The electrodes

From the Arthritis Department Cedars of Lebanon Hospital

were covered with hard rubber one-eighth inch thick. The electrode under the palm was $1\frac{1}{2}$ inches by three-sixteenths inch, over the affected nail an electrode nine-sixteenths by three-eighths inch was applied. Between the electrodes and the hand, towels about one-half inch thick were applied. The current was too small to register on the ammeter, which indicates tuning of the patient's circuit in resonance with the primary circuit. During the second treatment, however, the ammeter indicated 200 milliamperes. The child complained of a burning sensation. Treatment was interrupted immediately.

Fig. 2 (case 6)—Third degree burn of the calf of the left leg. Necrosis of the skin fourteen days after treatment.

The skin inside and below the nail was white. The finger was throbbing. Within twenty-four hours a blister the size of a five-cent piece (21 mm) had developed and burst, the red dermis was exposed. Healing was slow.

CASE 2—A woman aged 32, was treated with the 6 meter, 225 watt output ultra-short wave machine for stiffness of the phalangeal joint of the right thumb. Hard rubber electrodes 3 by 2 inches and a 1-inch padding of felt and towels were applied to the palmar and dorsal aspect of the right hand. During the third application, the patient complained of pain. The treatment was interrupted and two white spots were noticed.

Within four hours a blister formed (fig 1) over the protuberance of the base of the first phalanx of the thumb. The blister was punctured the next day, the dermis was very red. In the course of the next few days a grayish scab formed under which healing proceeded and was complete within two weeks.

CASE 3—A woman, aged 55, was treated for rheumatic pain over the lumbar spine with a 9 meter ultra-short wave apparatus of 150 watt output. Hard rubber electrodes approximately 5 by 3 inches were used over the lumbar spine and abdomen. Padding of towels was used. When I saw her there was an excoriation of the skin over the second lumbar vertebra about $1\frac{1}{2}$ by 1 inch. The base was formed of the corium. The burn had occurred two days before.

CASE 4—A middle aged man was treated over the chest for fulminant pneumonia with short wave apparatus of unknown wavelength. An extensive burn with destruction of the skin was produced. The man died of pneumonia.

CASE 5—A man was treated for sinus infection with a short wave apparatus. One rubber electrode was applied to the neck and the other over the face and nose. Severe burn and destruction of the tip of the nose was produced.

CASE 6 (reported by Dr. Berg)—A college student received short wave therapy consisting of approximately 3,000 milliamperes through the calf of the left leg. A representative of the company selling the machine was present while these treatments were being given. The electrodes were placed anteriorly and posteriorly with towel padding between. The duration of the treatment was about twenty minutes. No sensation of heat, burning or any discomfort whatever was noticed by the patient.

The electrodes were then placed one below the foot and the other over the knee. While 3,000 milliamperes was given with this placement the entire leg felt uncomfortably warm. Treatment was discontinued. Three small blisters on the dorsum of the calf were noticed on cessation of treatment. In two days it was apparent that an extensive burn had been produced.

Figure 2 shows the condition of the burn fourteen days later. The area measured 3 by $1\frac{1}{4}$ inches. There is now considerable sloughing of the superficial tissues and beginning granulation. This area will need a skin graft.

Figure 2 seems to show by the marking of the towels on the skin that the burn was produced while the electrodes were in the anterior-posterior position, during which time the patient experienced no discomfort of any sort.

EXPERIMENTAL BURNS¹

Fully developed rats were exposed under ether anesthesia, to the electrical field of the 6 meter ultra-short wave apparatus of 250 watt output. Hard rubber electrodes measuring $1\frac{1}{4}$ by $1\frac{1}{16}$ inches were used. They were applied for the treatment of the lower parts over the abdomen and back and for the treatment of the brain to both sides of the head. The rectal temperature was controlled during and after treatment by a mercury thermometer and was raised in only one case. Whenever the energy in the treatment circuit was small

Fig. 3—Experimental burn in a rat. Right hind leg has fallen off. Slough at the base of the tail. This is about twelve days after treatment.

no untoward general or local effects were noticed immediately or later. As soon as the energy was increased to register over 100 milliamperes on the tuning ammeter, however, burns developed in typical locations. When the electrodes were applied to the head, the burns involved the ears and fore legs, with the electrodes over the back and abdomen, the hind legs, base of the tail, testicles, penis and anus were

¹ Assistance in the animal experimentation was given by Mr. H. M. Rubin and Mr. H. J. Rubin.

involved. Sometimes, however, milder burns developed on the ears and forelegs, even when only the lower parts were treated. The burned skin immediately appeared grayish, singed or brownish red. Thin parts, such as the ears and limbs, shriveled, turned black, and fell off without perceptible bleeding or suppuration. The ears fell off in toto or in part within three to twenty days. The legs became contracted, the hip joint, above the burn was indurated, the legs fell off within two to nine days, exposing a black stump of the femur. These severe burns therefore offered a clinical symptomatology of dry gangrene (fig 3).

The thicker parts, the base of the tail, testicle and anal region, developed first sloughing of the skin and soft tissues, so that tendons and bone were laid bare, pus pockets formed and finally the tail separated, usually between nine and twenty-five days. One very small tail, which was directly treated, fell off in three days.

Over the abdomen, especially around the anus and penis, hard infiltrations developed, twice anal fistulas developed. The skin of the scrotum sometimes sloughed off in places. A very interesting edema of the fore leg developed in a rat treated over the abdomen (fig 3). The skin was bluish but intact. The edema which first was noticed over the wrist, seven hours after treatment, spread in the next days over the entire leg and persisted for two weeks. On the sixteenth day a small

Fig 4—Schematic drawing of skin with three sweat glands and sweat drops on the surface showing the concentration of the field produced by perspiration.

but deep slough developed and demarcation and suppuration were observed to precede healing. This slow healing, even of milder burns parallels the observation in patients.

THE MECHANISM AND THE PREVENTION OF BURNS

On the basis of observation and experimentation, the following factors seem to be responsible for the production of burns in the short wave electrical field.

1 *The Surface Effect*—It was found on cadavers that, for every rise of 1 degree centigrade in the femur, the temperature of the skin of the thigh rose 64 degrees. The accumulation of heat in the tissues adjoining the electrodes is augmented by unsuitable insulating material of the electrodes and padding, such as soft rubber and felt which heat up during the treatment. This surface heating is well illustrated by the following experiment.

A board 1 inch thick was placed between two round adjustable hard rubber electrodes (Schliephake electrodes). The maximum output of a 6 meter 225 watt machine was turned on. The temperature rise read on a mercury thermometer inserted in a hole in the middle of the board was 73 degrees C in a two minute period. When an air gap of one-half inch was formed between the board and the electrodes, the rise of temperature in the same period was only 7 degrees C or 10 per cent of the value without the air gap.

The interposition of air between electrodes and skin, producing an enormous loss of energy, forces the employment of powerful apparatus in order to treat efficiently, on the other hand, it is the surest means to eliminate the danger of surface accumulation of heat. Compared with the high resistance of the air, the differences between the tissues become very small, this makes the heating of the skin conform to the heating of the deep structures. None of the burns occurred with air gaps. For the prevention of accumulation of heat on

Fig 5—A acro-effect. Concentration of the field at the tip of the nose with danger of burn. Too close application and no leveling of the nose with the surface of the face. B correct application and padding of the nose and distance from the electrodes spread the field homogeneously.

the surface, the necessity of suitable distance of the electrodes from the skin is evident. This gap should be filled out by a good insulator that does not heat up under treatment. Adjustable air gap electrodes of a special glass were found most satisfactory, next came adjustable hard rubber electrodes. Soft rubber is the least desirable, it heats up readily, which decreases its dielectric properties and may also develop small defects through which direct current flow and sparking occur. Most machines in this country, however, are not equipped yet with air gap electrodes and therefore padding must be used between the electrodes and the skin. An absorbent material, such as cotton, rubber sponges or tissue paper, which does not heat so much, is to be preferred to the commonly recommended felt.

Fig 6—A acro-effect of the protuberance of the tibias between the knees. B correct application padding between the knees spreads the field homogeneously.

2 *Size of Electrodes*—The smaller the electrodes, the greater is the density of the electric field and the greater therefore the heating effect. With the apparatus previously mentioned but with electrodes about three times as large applied directly to the 1 inch thick board, the increase in temperature in two minutes amounted to only 5 degrees C. It is therefore necessary to decrease the energy of the apparatus or, better yet, to increase the distance of the electrodes from the skin in treating small areas such as the fingers or the

teeth Too little distance, with a very small electrode, was responsible for the burn over the nail in case 1

In thin areas, such as the fingers, it is possible that the surface heat of both electrodes creates a higher temperature in the deeper tissues than the skin. A burn could develop in the deeper structures over intact skin. This perhaps explains the peculiar edema of the foreleg of the rat shown in figure 3

3 *Perspiration*—Sweat contains electrolytes which transform the surface of the skin into a good conductor and decrease its resistance. The density of the field is therefore greater in the moist surface. This causes overheating and eventual burns (fig 4)

Sudden formation of sweat drops explains the rapidity with which burns were observed to occur under the treatment (fig 1, case 2). Control of sweating, by absorbent material or interruption of treatment is therefore necessary to prevent burns. Treatment over clothes, advertised as a great advantage over diathermy, should be rejected. It is not only unhygienic but dangerous. It promotes and at the time hides perspiration.

4 *The Acro-Effect*—This term, from the Greek *ἄκροι*, extremity, designates the action of a short wave electrical field on pointed parts such as the nose, ear lobes, finger tips, bony protuberances such as the olecranon tubercle of the tibia, spinous process of the vertebrae and base of phalanges. Here the areas are reduced to a minimum, the concentration of energy therefore is at a maximum, the pointed parts act like antennae. They were the common locations of the clinical as well as the experimental burns (cases 1, 2, 3 and 5). This concentration of current in pointed parts occurs even when they are in the middle of the field at the greatest possible distance from the electrodes. It is often noticed in treating both knees, by application of the electrodes at the outside of each knee, that the patient feels overheating first at the inside of the knees owing to this concentration of the field in the pointed protuberances of the medial condyles of the tibiae (fig 5). The greatest care must be taken to protect protuberances in every part of the field. By proper distance and padding (fig 6) the density of the field is made to spread homogeneously over the whole treated area. The nose is made level with the surrounding, the ears are strapped to the skull and the gaps between the tibiae are filled out.

SUMMARY

The widely circulated assumption that the use of condensor electrodes in short and ultra-short wave therapy excludes burns and simplifies the technic is a dangerous fallacy.

In six cases, three each of second and third degree burns, the first group produced slow healing blisters, the second total necrosis of skin.

Burns were produced in rats, ranging from edema to gangrene and loss of ears, limbs and tails.

Sufficient energy, proper electrodes and distance from skin, absorption of perspiration, and constant control of patient and apparatus are imperative in order to prevent damage and derive the benefits of short and ultra-short wave therapy.

Soda and the Cooking of Vegetables—The addition of soda greatly increases the rate of destruction of vitamin B, and should be avoided in so far as is practicable in the cooking of fruits and vegetables.—Sherman, H. C. Food and Health New York Macmillan Company 1934

AN ANEMIA ASSOCIATED WITH A FISH TAPEWORM (*DIPHYLLOBOOTHRIUM LATUM*) INFESTATION

THOMAS N. HUNNICUTT JR., M.D.
NEWPORT NEWS, VA

Many cases of infestation by the fish tapeworm have been reported in this country, principally in localities settled by emigrants from the Scandinavian countries. Magath,¹ in a recent paper on the Relation of *Diphyllobothrium latum* infestation to the public health, reviewed the literature exhaustively from the point of view of the mode of spread and the incidence of the foreign as well as of the native cases. He showed that the prediction of Stiles,² made more than a quarter of a century ago, that the infestation would soon become endemic in this country was now fully realized.

Magath asserts that the anemia of the fish tapeworm host when it occurs, is always of the primary type. He points out, however, that this is a very rare condition unless the literature of Finland is examined. Even then the incidence there, as reported by Ehrström,³ ranges from 1 in 5,000 to 1 in 10,000, but some have reported an incidence as high as 1 in 700. Magath thinks that other factors are at work when anemia occurs in the presence of infestation by this parasite, and, at best, the presence of *Diphyllobothrium* is considered only as a "trigger" that sets off the illness (anemia).

Schauman,⁴ who has been the foremost European investigator of this problem, maintains that *Diphyllobothrium* is capable of causing an anemia which is not distinguishable from true primary pernicious anemia and that the reason the incidence of the disease is so small is that the "ordinary host is refractory toward the anemia causing agent of the tapeworm."

Piney⁵ calls attention to the close resemblance between this anemia and true primary pernicious anemia. He also feels that this condition may be elicited in some by the toxins of the fish tapeworm but thinks there probably exists a constitutional predisposition in these patients. Clough⁶ classifies this anemia under the differential diagnosis of pernicious anemia, but he feels as Piney did that there are probably other factors than the mere presence of the worm.

Birkeland⁷ in a recent work, reviewed all the foreign as well as the American literature on bothriocephalus anemia, and, after presenting the observations and opinions of apparently all who have written on this subject, in an unbiased but critical manner, concluded that the anemia occurring in symbiosis with an infestation by *Diphyllobothrium* is probably not due to any specific substance elaborated by this parasite but to a constitutional factor which would probably cause this

type of patient to have a pernicious anemia without the presence of the parasite granting that there occurs some unknown precipitating factor in this disease. He considers patients who suffer and survive bothrioccephalus anemina as having had an abortive form of true primary pernicious anemia. He found no proof in his study that tapeworm anemia is a clinical entity.

Isaacs, Sturgis and Smith⁸ studied a patient with a fish tapeworm infestation who had a typical blood and

patient did state later that he had had worms as a child, was treated for them and had passed no segments since then. There was no history of any injuries or operations.

When first seen the patient's chief complaint was general weakness, right-sided headache, vertigo, nausea and vomiting. The present illness began a year before admission, when he noted a feeling of being below par most of the time and an insidious progressive general weakness until two months before, when it became very noticeable, interfering with his work. Accompanying this had been a dull right-sided headache and recently attacks of vertigo. For the past two weeks he had been frequently nauseated with the vertigo attacks and had vomited small amounts of undigested food. The vomitus had not been bile tinged, nor did it contain fresh blood nor had it been of a coffee grounds character. Several days previously friends had commented on the appearance of his skin, which was of a lemon yellow hue.

Physical Examination—He was well developed and fairly well nourished but appeared ill. The temperature was 99.4 F, the pulse 78 and regular, the respiration rate 22, and the blood pressure 110 systolic, 70 diastolic. The skin was lemon colored. There were no scars or eruptions. The head was normal in size and shape, the pupils were equal, reacting to light, and the sclerae were clear. There was no evidence of nasal disease. The lips were pale and all mucous membranes appeared anemic. The tongue was smooth but did not have the appearance of a typical glossitis, the teeth were sound. The pharynx and nasopharynx were not inflamed. The tonsils were atrophic. There was no stiffness or adenopathy of the neck. The thorax was symmetrical, with a free and equal expansion. The heart was not enlarged on percussion. The sounds were of good quality and there were no murmurs. The lungs were resonant throughout, with no rales. The abdomen was flat, there was no subcostal tenderness or muscle spasm. The liver edge was felt two fingerbreadths below the costal margin in the mid-clavicular line. It was smooth, firm and not tender. There were no abnormalities of the genitalia or extremities. The

Red cell count (solid line), hemoglobin (broken line), percentage of reticulocytes (dotted line) and course of the color index.

a clinical picture of primary pernicious anemia which was amenable to liver therapy before removal of the tapeworm and who had no relapse of the anemia following the eradication of the parasite, even when liver therapy was stopped. The patient's mother in this case had died of pernicious anemia. In their study, they seemed to think that the case was one of a tapeworm anemia, but they could not demonstrate the presence of soluble toxins by intradermal tests with saline suspensions of the tapeworm and they conceded that this might have been an incidental infestation in a true primary pernicious anemia.

Seyderhelm⁹ has demonstrated that the ground-up body of the fish tapeworm has a hemolytic action both *in vitro* and *in vivo*.

The present report is concerned chiefly with the question of anemia caused by or at least accompanying a case of fish tapeworm infestation and its response to liver therapy as well as the continued convalescence of the patient after removal of the parasite and the discontinuing of specific therapy for the anemia.

REPORT OF CASE

History—J. K., a man aged 24 born in a small fishing village in Finland, came to this country in 1921 at the age of 11 years and has lived in and around New York City since then working at odd jobs. For some time he has been employed as a houseman just outside the city. He has spent several winters in Florida in the last few years traveling with his employer.

The patient's father died at the age of 45 of 'rheumatism' but his mother is living and well (aged 70) and two sisters are living and well (aged 30 and 35). Two brothers are dead, they died in childhood of an unknown cause. There was no family history of anemia.

There was no history of previous illness until one year after the patient came to this country and then he had a mild attack of scarlet fever with no sequelae. The cardiorespiratory, gastrointestinal and genito-urinary histories were negative. The

sugar or acetone, the sediment contained a very occasional white blood cell. A specimen of stool was negative for occult blood.

The gastric analysis following an Ewald test meal showed no free hydrochloric acid and a total acidity of 4. The gastric contents contained 50 per cent of mucus. There was no lactic acid or occult blood. Five months later the laboratory examination was as follows: red blood cell count, 5,440,000, white blood cell count, 12,700, hemoglobin, 100 per cent (Sahli), color index, 0.92, differential count polymorphonuclear leukocytes 70 per cent (filament 51 per cent, nonfilament 19 per cent), lymphocytes 13.5 per cent, monocytes 10 per cent, eosinophils 0.5 per cent, basophils 1 per cent. The blood counts are given in the accompanying table.

Course and Treatment—Because of the nausea and vomiting, parenteral liver extract was given in the gluteal muscles, and after the first forty-eight hours the patient began to improve symptomatically and in seventy-two hours clinically. The red cell count rose and continued to increase steadily. There was a normal response of the reticulocytes. A graph of the blood examinations shows the hematopoietic response.

Approximately eight weeks after treatment was begun, the patient's blood was normal and he was carrying on his usual duties. Following the parenteral liver, which was given in maximum doses for ten days, he was given capsules of liver-stomach concentrate. This therapy was discontinued four months later, when the red cell count and the hemoglobin continued to be normal. He was then put on a liberal high vitamin diet.

The patient continued to be well but came in one month later complaining of the passage of an intestinal worm. A stool examination revealed ova of the fish tapeworm (*Diphyllobothrium latum*). Five months after the patient was first seen he was again admitted to the hospital and, after suitable preparation, oleoresin of aspidium was given (four 15 minims capsules). The next day, four apparently complete tapeworms were expelled, as well as many segments of varying lengths. Two weeks following this the stools still contained ova and it was thought advisable to give another anthelmintic. However, after a delay of a month before the second treatment was started, the stools became negative and remained so on several examinations. A gastric analysis done at this time showed a continued absence of free hydrochloric acid. On discharge, after eight months' continuous observation, the patient had no complaints and he appeared well, the red blood cell count was 4,988,000 with a hemoglobin of 98 per cent. Seven months later he came in for a check over. At this time he had no complaints except a mild constipation, which was controlled by the taking of liquid petrolatum. He had passed no segments of worms, and a blood examination showed a red cell count of 5,940,000 with a hemoglobin of 92 per cent.

SUMMARY

1 While it is granted that the anemia occasionally occurring in persons who harbor the fish tapeworm is always primary or pernicious in type, the evidence is not clear as to what factors cause this anemia. Some investigators doubt the probability that the presence of this parasite is one of them. They hold that these cases are true primary pernicious anemia occurring in certain people who happen to harbor the fish tapeworm. Many are of the opinion that these patients have a certain constitutional predisposition to anemia. Others have reported recovery from tapeworm anemia by removal of the parasite and feel that *Diphyllobothrium* is capable not only of precipitating an anemia but of directly causing one.

2 This patient apparently had been infected with the fish tapeworm since childhood, but symptoms of anemia did not develop until the age of 24. The pernicious anemia-like blood picture responded to liver therapy while the patient still harbored the parasite, and he continued to be well, except for an asymptomatic achylia,

after the discontinuance of the liver and the subsequent removal of the worm. The case was followed continuously for eight months and was seen again at the end of fourteen months.

3 In view of the time already elapsed (twelve months) without a return of the anemia and with no specific therapy during this period, it would seem that this is probably a case of a true tapeworm anemia.

ment on that paper has led us to insist on certain points. In the first place, these children were in an environment in which they were peculiarly subjected to the chance of infection, secondly, the group of partially breast fed includes two classes of children: (1) those who were entirely breast fed for a time and then had

¹ Grulee, C. G., Sanford, H. N., and Herron, P. H. Breast and Artificial Feeding. J. A. M. A. 103: 735-738 (Sept. 8) 1934.

to be weaned and (2) those whose breast feeding had been complemented. The artificially fed group consisted only of those children who had been artificially fed from the first. We took only those cases which had been under our care for nine months with the exception of those children who were under our care continuously until the time of death.

This study comprises the same group of infants mentioned in the former paper.¹

artificially fed the rise is steady through the ninth month. In the breast and artificially fed groups there is a fall after the seventh month.

The gradual rise in morbidity from all groups for the first six months might be explained in two ways. First, the infants are exposed to repeated infection. Second, some immunity may be inherited from the mother, which gradually lessens with age. In the breast fed and partially breast fed after the seventh month

according to age is given in months, with the exact number of cases recorded for each month. With this information is given the percentage of these cases to the total number of infants in that group. These percentages are also expressed graphically.

Table 2 gives the mortality with the age in months and the percentage of the total as in

there is a gradual decrease in morbidity. Since at this time there is a marked rise in the curve for the artificially fed, it would seem likely that breast milk continued the immunity longer than the sixth month, while this function was removed in the artificially fed. The drop in the curves after the seventh month in both the breast fed and the partially breast fed groups may be the result of the protection that the increased period of life has given.

In the gastro-intestinal morbidity, there were not enough breast-fed infants with these disorders to calculate the percentage. Breast milk evidently guards the baby against gastro-intestinal disturbances. The peak of the par-

Chart 4—Monthly mortality respiratory infections.

Chart 5—Monthly mortality gastro-intestinal disturbances. This graph is somewhat deceptive in that the highest mortality occurred from September 29 to October 4. Really the peak comes the last of September or the first of October.

Chart 6—Monthly mortality unclassified infections.

the morbidity. These percentages are also expressed graphically in the charts.

RESULTS

In the respiratory infections, it will be noted that for the first five months of life, while there is not a great deal of difference in the total incidence, there is a rise in all groups to the fifth month. The morbidity decreases after the sixth and seventh months in the breast and partially breast fed groups, while in the

Both decrease rapidly as the child becomes older and evidently more tolerant to food.

The miscellaneous morbidity is somewhat similar to that of the respiratory disturbances. All types show a rapid rise to a peak at 5 months. The artificially fed curve, however, continues to rise to the eighth month and then falls.

trially breast fed infant is at 5 months, while that of the artificially fed infant is at 7 months.

We might say, therefore in general that in all types of feeding the morbidity from infection increases each month until the fifth month. In the breast fed and partially breast fed it then decreases through the ninth month. In the artificially fed baby it continues to increase through the ninth month. From the gastro-intestinal disorders the breast fed baby is practically free, while the incidence for the partially breast fed baby increases to the fifth month and then decreases to the ninth month, and for the artificially fed baby increases to the seventh month and then decreases to the ninth month.

From the mortality curves the breast fed baby appears to be in danger only in the first month of life. The greatly increased mortality of the artificially fed baby in all months is very evident. In the respiratory infections for the first four months it is high, then decreases and rises again at the ninth month. The curves for the first four months are high for the artificially fed baby both in the gastro-intestinal disturbances and in the unclassified infections. In both instances there is a drop at the fourth month and almost a leveling of the curve through the ninth month.

CONCLUSION

In the survey, according to age by months, of the morbidity and mortality for 20,000 infants, two things are most significant. First, there is a definite rise in the

The Tougher Meat Is Nutritive—Aside from the effect of market conditions, the price varies with the cut of meat purchased. There is a general preference for the tender cuts, which makes them more expensive. However, all parts of the carcass containing a large proportion of muscle are equal in nutritive value and with skilful preparation the tougher, cheaper cuts may be made very palatable—Newburgh, L. H., and Mackinnon Frances, *The Practice of Dietetics*, New York, Macmillan Company, 1934.

GYNECOMASTIA DURING HYPERTHYROIDISM
REPORT OF TWO CASES
PAUL STARR M.D. CHICAGO

Gynecomastia is not an exceptionally rare condition. Various associated pathologic processes have been reported. Three reviews¹ have recently appeared. An excellent discussion by Hammett² appeared in 1920. Freeman's case of hyperthyroidism is mentioned. These reviewers do not include hyperthyroidism as a possible immediate cause of gynecomastia, their attention being centered on the influence of gonadal hormones. The cases to be described are significant because of the appearance of the anomaly during hyperthyroidism and its disappearance with the surgical interruption of the disease.

Fig. 1 (case 1) — Breast hypertrophy during hyperthyroidism

Such an association must be unusual or have gone unnoticed as it has rarely been reported, although von Basedow³ in 1848, while commenting on the suppression of sexual functions and the atrophy of the breasts in women due to this disease, stated that he had observed a man with hyperthyroidism who had swollen breasts which secreted colostrum. In Allen's⁴ review two specimens are from patients with associated hyperthyroidism. Freeman⁵ in 1916 briefly described a case in which a man, aged 37, the father of four children, developed bilateral gynecomastia three months after the symptoms of hyperthyroidism began. The effect of the further course of the disease was not mentioned. Besley⁶ mentions a boy with gynecomastia who had goiter, exophthalmos, tremor and tachycardia. Sterling⁷ in 1932 briefly reported three cases. In one of these the onset of the hyperthyroidism and gynecomastia was simultaneous. In a fourth extraordinary case, a boy aged 16 years, had had

progressive enlargement of the breasts since he was 9 years of age, operative removal of the breasts was followed by post-operative myxedema similar to that after thyroidectomy.

REPORT OF CASES

CASE 1—H. R., a white man, aged 45, married, a painter, was born in the goiter belt. He had had mumps orchitis, and testicular atrophy when he was 8 years old. A goiter was noted at 18 years and persisted to the time of admission. By a first marriage at 26 years he had a normal child. A second marriage at 41 had resulted in no issue. During the past two years sexual continence had been enforced by the ill health of his wife. Localized epigastric hunger distress, relieved by eating, began a year before admission to the clinic. Tremor, loss of weight, palpitation, dyspnea and finally exophthalmos began six months before observation. He states that enlargement of the breasts was noted during this time.

6 Sterling W. Les correlations endocrines des mamelles. Rev. neuro. 1: 141-142 (Jan.) 1932.

The patient was 5 feet, 8 $\frac{3}{4}$ inches (175 cm) tall and weighed 137 pounds (62 Kg), the upper body measurement was equal to the lower. The pulse was 94 and regular, the temperature 98.2 F, and the blood pressure 114 systolic, 80 diastolic. Beard growth was normal, the voice was masculine. A lag of the lid and staring indicated exophthalmos. Tremor was marked. The tonsils were large. Many of the teeth were decayed. The thyroid was enlarged and nodular. The chest and heart were clear. The breasts were conical, resembling the adolescent female development. No colostrum was present (fig 1). The penis was normal, both testicles were atrophic. There was female distribution of pubic hair. The basal metabolic rate (preoperative) was +31 and +24, after compound solution of iodine it was +20 and +14.

Because of hemorrhage during the operation only right hemithyroidectomy was done, but under continued compound solution of iodine postoperatively the basal metabolic rate dropped to +4. The left thyroid remained palpable and nodular. The conical hypertrophy of the breasts rapidly receded during the postoperative remission of hyperthyroidism. Six weeks after operation compound solution of iodine was discontinued. Two weeks later the metabolic rate had risen to +13, one month later to +28 with a loss of 8 pounds (3.6 Kg) from the

morphonuclear leukocytes 44 per cent, lymphocytes 54 per cent, eosinophils 5 per cent. A roentgenogram of the chest was negative. The urine was normal. Roentgen examination of the sella turcica was negative. The basal metabolic rate before compound solution of iodine was +49 and +54, after compound solution of iodine, +19 and +16. One month after operation without compound solution of iodine it was -3 per cent.

Fig 2 (case 2)—Diffuse goiter and hypertrophy of right breast during hyperthyroidism note emaciation

Fig 3 (case 2)—Appearance after operation. Thyroidectomy, scar and atrophy of breasts note increased subcutaneous fat

During examination, before treatment, sudden deep sleep would occur during any time that the patient's attention was not required. One month after thyroidectomy, although a gain of 16 pounds (7.3 Kg) had occurred, the metabolic rate was normal and the pulse rate subnormal, there was no suggestion of narcolepsy and the right breast had atrophied to the normal male condition (figs 3 and 4).

In the first case it is surprising that the gynecomastia did not occur in earlier years as a result of atrophy of the testicles,

Fig 4 (case 2)—A appearance during hyperthyroidism B after operation with normal metabolic rate

as in Tellgmann's⁷ case of unilateral hypertrophy after accidental destruction of one testis. It was necessary for hyperthyroidism to occur to establish the condition requisite for the production of breast hypertrophy.

The unilateral recurrence of gynecomastia on the side of the unoperated remaining thyroid lobe is also of great interest. Tellgmann suggests that the one-sidedness indicates a nervous

⁷ Tellgmann. Unilateral Gynecomastia After Loss of Testis. Deutsche med Wchnschr 52:2137 (Dec 10) 1926

highest postoperative weight, and tachycardia recurred. It was evident that a return of the hyperthyroid state had occurred. During this recurrence the left breast (on the unoperated side) enlarged. Further management was prevented by failure of cooperation by the patient.

CASE 2—A single man, aged 28, a carpenter born in Canada whose family history showed no goiter in the parents or nine siblings, had had no significant previous illnesses. There had been a loss of 30 pounds (13.6 Kg) with nervousness, palpitation, tachycardia, sweating, tremor, weakness and the appearance of a goiter during the past year. Narcolepsy had also been definitely associated with these symptoms. Enlargement of the right breast was noted two months previous to admission.

The patient was 5 feet, 7 inches (170 cm) tall and weighed 144 pounds (65.3 Kg). The pulse was 104, the temperature 98.2 F, and the blood pressure 135 systolic, 55 diastolic. The skin was sweaty. There were a slight lid lag and staring. Tremor was present. There was diffuse lobulated goiter with bruit. The lungs and heart were not abnormal. The right breast was conical, with a base of glandular tissue 2 cm in diameter (fig 2). The left breast was questionably hypertrophied. The external genitalia were normal.

The blood Wassermann reaction was negative. Red blood cells numbered 4,780,000, white blood cells 7,950 with hemoglobin (Sahli) 75 per cent. The differential count was poly-

cause, whereas the coincidence with recurrent hyperthyroidism demonstrates that a hormone factor is present

In the second case the unilateralness was also evident. The additional feature of narcolepsy is unusual. Its coincidence with the hyperthyroidism and disappearance with its removal, exactly as was true of the gynecomastia, suggests that the same immediate exerting force (thyroid hormone) produced both abnormalities.

A physiologic study by Weichert and Boyd⁸ may indicate the mechanism involved in these cases. They found that feeding thyroid to pregnant rats produced earlier and much greater hypertrophy of the breasts than occurred in control pregnant animals. Their explanation rests on their previous finding⁹ of the production of pseudopregnancy by thyroid feeding. Their general theory is that hyperthyroidism interferes with theelin effects either by raising the tissue resistance to theelin, by destroying theelin, or by causing its excretion. The breast tissue then is under the unopposed influence of the pituitary.

It seems to be a tenable theory that in these cases hyperthyroidism enhances certain pituitary hormone action on the gonads and mammary glands. Primary pituitary action seems unlikely because of the abrupt cessation of the associated conditions with the interruption of the hyperthyroidism.

SUMMARY

In two cases of hyperthyroidism gynecomastia appeared and disappeared with the onset and interruption of the primary disease.

A WATERPROOF LAPAROTOMY PAD OF GAUZE AND CELLOPHANE

FRANK H. LAHEY, M.D., BOSTON

A cellophane pad that I devised has now been employed for more than two years. A description of it together with the illustration is presumed with the possibility that it may prove useful to others.

It consists of a pad measuring 14 by 16 inches in the center of which is a layer of cellophane on each side of which are two three or four thicknesses of gauze either with selva edges or with the edges turned in. A layer of stitching an inch or two from the edge of the gauze is carried around the entire pad, thus fixing the cellophane in place.

The advantages of this pad are particularly that it is waterproof so that it can be used to drape over wound edges during gastric and colon resections, thus protecting them from contamination. It can be sterilized in the autoclave with no ill effects and has the advantage when wet of being as soft and flexible as though no cellophane were included between the layers.

A diagrammatic illustration is included to show the pad itself.

Illustration *a* shows a face view of the pad, *b*, an edge on view to show the cellophane center.

FOREIGN BODY ABSCESS OF THE PANCREAS

ROBERT S. BALDWIN, MARSHFIELD, WTS.

Although diffuse pancreatitis occurs with sufficient frequency to warrant its being included in the differential diagnosis of most abdominal disorders, a localized suppurative process in the pancreas is rarely seen.

I report here the observations made on a patient with an abscess of the head of the pancreas which surrounded a foreign body resembling a toothpick. So far as I could determine, no similar case has been observed heretofore.

REPORT OF CASE

J. M., a man, aged 40, a farmer, was admitted to the hospital, July 18, 1934, after a tentative diagnosis of typhoid had been made. He said that his illness had begun three weeks previously with an infection of the upper respiratory tract. Chills and fever, epigastric pain, vomiting and diarrhea occurred soon afterward, and he had been in bed for two and one-half weeks. In addition, he noticed loss of appetite, headaches and dark colored urine. Ten years before admission, the appendix had been removed.

On physical examination he had a temperature of 104 F., a pulse of 140, and a respiratory rate of 28. He was well developed and well nourished and looked acutely ill. His skin was deeply icteric and dry. The liver was tender and extended three fingerbreadths below the costal arch. The diagnosis was liver abscess, also empyema of the gallbladder, tularemia, typhoid and malaria were considered.

Several specimens of urine contained large quantities of albumin, many erythrocytes and leukocytes. The erythrocyte count was 4,220,000 and the hemoglobin was 70 per cent. Leukocytes numbered 19,450 with 93 per cent polymorphonuclear neutrophils. The icteric index was 25. Three blood cultures were negative. The blood Wassermann reaction was negative, there were no agglutinins for typhoid, paratyphoid, *Brucella abortus* and *Bacterium tularensis*. Malaria parasites were looked for several times but were not found. On one occasion the bleeding time and clotting time were one minute and three minutes respectively. The resistance of the erythrocytes to hemolysis was increased. No urobilin or urobilinogen was found in the blood. Bile was demonstrated in the stools. No typhoid organisms were demonstrated in the stool and urine. An elevation of the right diaphragm was seen on a roentgenogram of the chest.

The chills continued, as many as six or seven in twenty-four hours were observed, with rises of temperature to over 107 F. Six days after admission, because of the possibility of an empyema of the gallbladder, the right upper quadrant was explored. The liver was enlarged and mottled. The spleen was small. The gallbladder contained no stones and appeared normal. It was drained. In the sections made from a biopsy of the liver, only swelling of the liver cells was noted. Following the operation, slightly bile-stained material drained from the wound. The chills and fever persisted, the jaundice deepened, the icteric index rose to 80, and the hemoglobin dropped steadily in spite of two blood transfusions. After six weeks in the hospital the patient became irrational, his strength and state of nutrition failed rapidly and he died forty-eight days after admission, during the eleventh week of his illness.

The postmortem examination was made eight hours after death. The essential changes were as follows. The lungs were studded with multiple abscess cavities up to 1 cm. in diameter, containing thick greenish gray purulent material surrounded by zones of confluent bronchopneumonia. The liver was enlarged to 32 by 22 by 7.5 cm. and presented on the anterior surface of the right lobe a group of grayish yellow irregular slightly raised areas involving a region 5 cm. square. When the liver was cut into these areas were seen as the outer walls of abscess cavities. Other cavities up to 2.5 cm. in diameter were found throughout the right lobe. They communicated with the intrahepatic bile ducts, which were distended and filled with thick grayish yellow purulent material. When the hepatic duct was followed toward the duodenum, no connection with the cystic duct was found, but it was seen to communicate with an abscess cavity 3 cm. in diameter in the head of the pancreas, in which was embedded a foreign

body of woody consistency, 4 cm long and 1 mm in diameter. The main pancreatic duct was 15 cm in diameter and was filled with purulent material. The gallbladder was small and contained a thin yellow stained fluid. It was bound to the anterior abdominal wall and its cavity communicated with a fistulous tract that led to the skin. The cystic duct and common duct formed a continuous passage to the duodenum, which had no communication with the hepatic duct. The common duct was 8 mm. in circumference. Its mucosa was thin, slightly corrugated and stained yellow. The first portion of the duodenum contained a dirty greenish yellow purulent material, its mucosa was injected and edematous.

SUMMARY

In this patient a foreign body was found in an abscess cavity in the head of the pancreas. The abscess cavity had ruptured into the pancreatic duct and into the hepatic duct, giving rise to an ascending suppurative cholangitis and multiple liver abscesses. From here the infected material was carried to the lungs, producing multiple abscesses. The brain was not examined, but the patient presented symptoms of cerebral involvement during the last few days before death, indicating a metastatic spread to the brain with the formation of abscesses.

GLANDULAR PHYSIOLOGY AND THERAPY

SEX-ENDOCRINE FACTORS IN BLOOD
AND URINE IN HEALTH
AND DISEASE

ROBERT T. FRANK, M.D.
NEW YORK

NOTE.—This article and the articles in the previous issues of THE JOURNAL are part of a series published under the auspices of the Council on Pharmacy and Chemistry. Other articles will appear in succeeding issues. When completed the series will be published in book form.—Ed

The modern concepts of endocrinology have made it necessary to revise the obsolete humoral pathology of the ancients, which predicated four essential "humors"—blood, phlegm, black bile and yellow bile. Before the presence of hormones circulating in the blood had been demonstrated, the interpretation of many phenomena could be explained only by a humoral hypothesis. Today this hypothesis has been verified.

The first direct evidence by a specific test of hormones circulating in the blood was offered simultaneously and independently by Loewe¹ and his collaborators and by me and my group.² Since then other hormones have likewise been demonstrated in the circulation.

This contribution aims to show, as well as present limited knowledge permits, the content, both qualitative and quantitative, of the sex endocrine factors in the blood stream and excretions, and their variation under different physiologic and pathologic conditions. Clinically this evidence is of great importance, as it aids both in diagnosis and in evolving and carrying out therapeutic measures, as well as to some extent in explaining the disheartening failures that are so often encountered.

HISTORICAL

The researches of many investigators extending over a century have been necessary to furnish the little information that is available today.

In 1849 Berthold,³ by transplanting the testes of cocks into other castrate cocks, with restoration of the male primary and secondary sex characters, offered convincing but indirect proof of the circulation of an internal secretion of the male gonad. This basic observation attracted little attention at the time and was forgotten for half a century. In 1896 Knauer⁴ obtained similar evidence in the female by successfully transplanting ovaries into animals of the same species. In 1905 Halban,⁵ by means of purely clinical data showed that the placenta was an organ of internal secretion. Every one of his contentions has since been verified by experimental proof. In 1907 Leo Loeb⁶ produced "experimental deciduomata"—maternal portions of the placenta which, as he showed, were due to the special corpus luteum hormone, now commonly called progesterin. From 1912 on, Iscovesco⁷ and soon thereafter Aschner,⁸ Fellner,⁹ Herrmann,¹⁰ and Rosenbloom and I,¹¹ as well as others, prepared active extracts from the ovary and placenta, which caused estrogenic reactions on the uterus of castrate or immature animals.

All research on the estrogenic substances has been speeded up since 1923, when Allen and Doisy¹² published their simple, rapid and specific test for the qualitative and quantitative determination of these substances. The old progesterin test of Boun and Ancel¹³ has recently been revived, with modifications, to demonstrate both qualitatively and quantitatively the presence of the special nidatory corpus luteum hormone "progesterin."

The fundamental discovery of Smith¹⁴ in 1925 and that of Zondek and Aschheim¹⁵ shortly afterward that both ovary and testis remain dormant unless stimulated by the secretion of the adenohypophysis (anterior pituitary or prepituitary gland) and that this gonadotropic factor activates alike the gonads of the two sexes, changed all previous concepts. All evidence points to the thesis that the adenohypophysis is the "master" gland. It in turn may be influenced by other endocrine organs.

Knowledge of the testis hormone has been slowly but steadily increased since McGee¹⁶ in 1927 succeeded in obtaining active lipid extracts of the testes. The test for the testis hormone has been less clear cut and less rapid than that for the estrogenic hormone in the female, but by means of the capon test (comb, wattles

and spurs) (Walker,¹⁷ Pezard¹⁸) as well as the various tests based on regeneration of seminal vesicle and prostate function, elaborated simultaneously and independently by Moore¹⁹ and Loewe,²⁰ considerable advance has likewise been obtained

At the present time the prepituitary gonadotropic factor or factors, estrogenic substance and progesterin as well (the special corpus luteum hormone, nidatory or "pseudopregnancy" hormone) have been demonstrated in the blood stream and urine. A number of the sex-endocrine principles have been recovered from the placenta, bile, sweat, saliva and cerebrospinal fluid

NORMAL FEMALE

In the normal female the following hormones require consideration

1 (a) The bisexual gonadotropic hormone or hormones of the adenohypophysis (Smith,²¹ Zondek²¹)

(b) The bisexual anterior pituitary-like factor found in the blood, urine and placenta (Smith,²² Zondek,²¹ Collip²³), which does not give a complete reaction in hypophysectomized animals²⁴

2 The estrogenic factor (Iscovesco,²⁵ Fellner,⁹ Frank and Gustavson,²⁵ Allen and Doisy¹²)

3 The corpus luteum hormone (nidatory or pseudopregnancy factor) (Fraenkl,²⁶ Bouin and Ancel¹³ Leo Loeb,⁶ Corner²⁷), "progesterin"

4 The testis hormone (Loewe²⁸)

Each of these hormones can be demonstrated by specific tests. The interpretations of some investigators cannot be accepted fully because of failure to employ adequate methods. For example, titration of the prepituitary-like gonad stimulating principle or the prepituitary gonadotropic factor based on the reading of the vaginal spreads of immature rodents, without study of the sectioned ovaries, is inconclusive. Smith²² has proved his contention that, to distinguish these two factors, hypophysectomized mice or rats must be employed

All my gonadotropic titrations were performed on animals not deprived of their hypophyses. Therefore they are recorded as "anterior pituitary gonadotropic

factor," which may prove to be either the one or the other (that is, either 1a or 1b) on further investigation

Normal Prepuberal Female—In the early years little or no gonadotropic factor or estrogenic factor can be detected in the blood or urine. Katzman and Doisy⁹ found that the amount of gonadotropic factor excreted in the urine of prepuberal girls in twenty-four hours was less than from 2.4 to 3.7 rat units. Even before the onset of menstruation a cyclic excretion of estrogenic substance in the urine has been noted, as shown by our observations on three children

One mouse unit at 4 years in 500 cc. of urine

One mouse unit at 9 years in 250 cc. of urine

One-half adult amount at 12½ years, two and one half months before first menstruation, cyclically excreted

Normal Adult Cyclic (Menstruating) Female—Both gonadotropic and estrogenic principles occur cyclically in the normal, adult female in the blood and urine. There is evidence of a progesterin cycle (Loewe) in the urine (to be shown later). A substance having the effects of the testis hormone is regularly found in the urine of females, as shown later (Loewe, Laqueur). Chart 1, based on more than 150 normal subjects, shows the details of these cycles in the blood and urine

Blood—Chart 1 shows that in the circulating blood approximately nine days after the onset of the preceding period, 25 rat units per liter of gonadotropic factor is found. Before and after this date the amount is less.³⁰ The estrogenic factor gradually increases to 25 mouse units per liter within one week of the anticipated menstruation and with the onset of the flow rapidly (within from two to six hours) disappears from the blood (i.e., less than 1 mouse unit in 40 cc.)

Estrogenic substance injected into the blood stream rapidly disappears from the circulation. As much as 2,000 mouse units injected into a rabbit had disappeared within one-half hour and could not be detected in the urine or tissues in twenty-four hours.³¹ The mechanism of this disappearance could not be determined

On the other hand, a concentration of estrogenic substance is found in the menstrual blood. It may attain from five to six times the concentration found in blood simultaneously drawn by wet cupping from the punctured portio vaginalis of the same patient.³²

The upper blood level and excretory threshold for both gonadotropic and estrogenic factors appear to be constant and extremely delicately balanced, as will be shown later

Urine—The cycle of the gonadotropic factor in the urine has not been fully determined. Kurzrok³³ finds 1 rat unit to 60 cc. at the eleventh to the fourteenth day after the onset of the preceding menstruation and less at other times of the cycle

The occurrence of estrogenic substance has been thoroughly studied by Frank and Goldberger³⁴ and

24 The different ovarian responses obtained by means of anterior pituitary gland extracts, pregnancy urine and urine of castrates (or menopause) are confusing. Further differences are noted depending on whether the test animal has been hypophysectomized or not. For the present I consider it unwise in attempt to draw far reaching conclusions from these variations. Accordingly one can distinguish in the hypophysectomized animal between (1) a full pituitary reaction due to gland extract which induces growth of the follicle, ovulation and corpus luteum formation, (2) follicle stimulation (menopause and castration urine) (3) thecal and interstitial cell growth (pregnancy urine). The significance of these reactions is still a matter of doubt

by others (Siebke³⁵) The entire quantity excreted in thirty days amounts to about 1,500 mouse units. Considerable variations are encountered, but two periods of maximum excretion, the first corresponding to the theoretical time of full follicle ripening or ovulation (fourteenth day), and the second in the last week preceding the menses, are characteristic (chart 1)

The chronological correspondence of increase in the estrogenic factor in the blood and increase of excretion in the urine demonstrates the great secretory activity of the ripe follicle and the active corpus luteum

Physiologic Menopause—When the climax is fully developed, no estrogenic substance is found either in the blood or in the urine. In 50 per cent of these women the content of gonadotropic factor is greatly increased in the blood (Zondek,²¹ Fluhmann³⁶). It may reach the high amount of 500 rat units per liter in contrast to the maximum norm in the cyclic female of 25 rat units per liter

Estrogenic substance may be found in the blood and urine of women as long as from one to two years after onset of the menopause. It is often noted in younger amenorrheic women who, following a shorter or longer period of amenorrhea, again begin to menstruate. Before menstruation has reappeared,

such changes are of diagnostic significance, ruling out the premature menopause. Smith²² has shown that the gonadotropic factor excreted in the menopause differs from the anterior pituitary-like gonadotropic factor from the urine of pregnancy and resembles that from the hypophysis itself.

MANIFESTATIONS IN DISEASE

As early as 1914, long before the primary importance of the adenohypophysis had been discovered, I³⁷ emphasized that the response of the ovaries to stimuli, no matter what their source, could manifest itself only in one of two ways—underfunction or overfunction. This concept has been amply confirmed. The primary stimuli (or their absence) arise mainly, or perhaps exclusively, from the adenohypophysis and act on the ovaries.

Underfunction of the Ovaries—In amenorrhea, oligomenorrhea and purely functional sterilities, and often also in dysmenorrhea, ovarian inactivity is recognizable by reduction in the amount of gonadotropic and estrogenic factors in the blood and the urine. These changes are readily visualized in chart 2, graphs B, C and D. The variations noted may show quantitative reduction in both blood and urine (subthreshold cycle), acyclic blood with reduced but typical urinary excretion, or complete absence of both blood and urinary cycles.

As the patients belonging to these three hormonal groups usually are clinically indistinguishable, accurate prognosis will depend exclusively on the hormonal changes, unless marked obesity or determinable thyroid or pituitary disease can be recognized, in which circumstances the prognosis will depend also on the gravity of the underlying primary endocrine disease. An impending return to normal conditions manifests itself by a reestablishment of normal blood and urinary hormone changes.³⁸

Artificial Menopause—An extreme degree of underfunction (absence of function) may be caused by operative or roentgen castration. Estrogenic substance is absent from blood and urine. The gonadotropic factor may be found increased as early as the tenth day after operation. More usually the increase, which is noted in at the most 50 per cent of the patients, develops after eight weeks and may persist indefinitely (Fluhmann³⁹).

Removal of the uterus, with retention of the ovaries, does not affect the blood or urinary gonadotropic or estrogenic cycle.³⁸ The same applies to nature's experiment—absence of vagina (uterus solidus)—in which not only has a normal cycle been determined³⁸ but among these cases instances of ovarian overfunction, as shown by the hormone graph, have been observed.

Chart 1—Hormone cycle (E S and A P) of normal fertile menstruating woman. Above base line (0) record of blood specimens taken every seven days. Black dots E S estrogenic substance (solid line), small circle, A P anterior pituitary gonadotropic factor (broken line) above $2\frac{1}{2}$ = positive below $2\frac{1}{2}$ = negative i.e. less than 1 mouse unit in 40 cc of blood. Below base line, total excretion of estrogenic substance in urine. Figures to the left show amount in mouse units. Total excretion 1,500 mouse units of estrogenic substance. Each block represents three days. A B C to show that single blood and urine specimens are valueless and misleading.

Chart 2—Occurrence of estrogenic substance (F S H) in the blood and urine of normal and amenorrheic women. A normal B subthreshold C negative blood cycle positive urine cycle D acyclic

Overfunction of the Ovaries—In the overfunctional group, excessive secretion, manifested by excessive excretion of estrogenic substance, is observed. The primary prepituitary cause can rarely be determined. These patients appear constitutionally normal except

39 Fluhmann, C. F. Anterior Pituitary Hormone in the Blood of Women. Endocrinology 15: 177 (May/June) 1931.

for precocious puberty, puberty bleeding, menorrhagia or metrorrhagia. In this group the concentration of gonadotropic factor in the blood may be normal. The estrogenic factor in the blood is normal or reduced but is markedly increased in the urine. Instead of about 1,500 mouse units in thirty days, as much as from 4,000 to 10,000 mouse units may be excreted.³⁸ In excessive bleeding due to fibroids of the uterus or pelvic inflammatory disease there may be no increase in the amount of estrogenic substance excreted.³⁸

In rare instances, overfunction is unaccompanied by excessive uterine bleeding. In so-called premenstrual tension, manifested by marked psychic and physical disturbances,⁴⁰ the excretion of estrogenic substance is markedly diminished, the estrogenic factor in the blood being increased to the level otherwise observed only in pregnancy (chart 3). This is interpreted as an elevation of the urinary threshold manifested by diminished excretion.

In absence of the vagina, a congenital malformation, the ovaries may oversecrete as evidenced by an excessive excretion of estrogenic substance in the urine.

Chart 3—Contrasting premenstrual tension and normal function. Normal estrogenic substance in blood shown by solid line; tension estrogenic substance in broken line. Tension shows increased estrogenic substance in blood. Decreased excretion totaling 300 mouse units (solid blocks) compared to that of normal female which amounts to 1,500 mouse units (dotted area).

Manifestations in Organic Diseases—As previously mentioned, no increase in estrogenic substance is observed in fibroids of the uterus and pelvic inflammation, even when accompanied by excessive uterine bleeding. The observations on the gonadotropic factor are incomplete and as yet afford no clue.

In precocious puberty due to ovarian tumor the estrogenic factor has been recovered from the urine and has disappeared after removal of the growth.⁴¹

Varying quantities of estrogenic substance have been recovered from ovarian carcinoma, sarcoma, teratoma,⁴¹ and adrenal carcinoma.⁴² Larger amounts of estrogenic principle are found in chorionepitheliomas irrespective of their source (uterine, ovarian, ectopic, testis), as will be shown later. In two cases of adrenal carcinoma with liver metastases (full autopsies including pituitary gland), the blood assays were normal but excessive

quantities of estrogenic substance were excreted in the urine (57,000 mouse units in thirty days). The pregnancy tests were negative. Clinically, this was a typical syndrome of "basophilic adenoma" (Cushing). This is even more surprising because the ovaries in both cases were in an atrophic condition without corpora lutea. No such excessive excretion has been encountered by us except during pregnancy. Similar syndromes ascribable to adrenal hyperplasia did not show these changes.⁴²

Mental Diseases—The report of underfunction of the ovaries in schizophrenia⁴³ appears to have no significance, as underfunction has been observed in many unrelated diseases.

Progesterin—Progesterin has not been demonstrated in the blood. I cannot accept Hisaw's observations⁴⁴ in which the relaxation of the pelvic ligaments of the female guinea-pig was employed as a test. The experiments of Kelly and Florence⁴⁵ likewise appear inconclusive. Their test consisted in observing inhibition of ovulation, the serum of pregnant women being used.

Loewe⁴⁶ has found 1 rabbit unit of progesterin in 20 liters of the urine of cyclic women in the five day period preceding menstruation. In all the other five day periods of the cycle, none was demonstrable. He employed the Bouin and Ancel test.⁴⁷ Chart 4 shows the time relation of pituitary estrogenic and progesterin cycles.

PREGNANCY

Normal—Within the first week of impregnation, a marked increase of the gonadotropic factor occurs both in the blood and in the urine. On this dramatic change the pregnancy tests of Aschheim and Zondek⁴⁷ and of Friedman⁴⁸ are based (chart 5).

In the nonpregnant cyclic female, at most 25 rat units per liter of gonadotropic factor is found in the blood by means of the concentration test and then only between the eighth and the tenth day of the cycle. In the pregnant female as much as from 10,000 to 20,000 rat units per liter has been found.²¹ By improved methods recently we have recovered as much as 40,000 rat units per liter in blood and urine (unpublished).

In the urine of the nonpregnant female, 16 rat units per liter of gonad-stimulating principle can be recorded on the fourteenth day.²¹ In pregnancy from 5,000 rat units per liter to 20,000 rat units per liter is excreted throughout pregnancy.²¹ These high titers persist until shortly after labor (from forty-eight to ninety-six hours), the level then drops to the nonpregnant norm unless chorionic tissue remains adherent to the uterine wall.

The blood estrogenic factor remains unchanged until the eighth week of gestation. It then rises from 25 mouse units per liter to 50 mouse units per liter and persists at this higher level until labor occurs. Zondek²¹ gives higher values, namely, from 200 to 300

mouse units per liter in the fourth month, and from 800 to 1,000 mouse units per liter at term. The urinary excretion of estrogenic substance increases gradually after the first week of pregnancy and by the later months may reach 20,000 mouse units per liter.²¹

This increase in estrogenic substance is not, however, sufficiently pathognomonic to permit of utilization as an early pregnancy test, although Mazer⁴⁰ has recommended it as a test (with 25 per cent error, the

Chart 4—Correlation of prepuitary estrogenic and gestational cycles in blood and urine of the normal adult woman. Progestin has not been demonstrated in the blood. This part of the graph is hypothetical.

Abbreviations used in the charts are as follows: A P H anterior pituitary gonadotropic hormone; A P L anterior pituitary like gonadotropic factor; A P F, gonadotropic factor (either A P H or A P L); E F estrogenic factor; R U rat unit; R U L rat units per liter; M U mouse unit; M U L mouse units per liter.

Aschheim-Zondek test in general showing not more than 2 per cent error).

Pregnancy Abnormalities—Fetal death is marked by reduction in the blood estrogenic factor within twenty-four hours, the urinary pregnancy tests (for gonadotropic factor) persisting for days. We have used this change in the amount of estrogenic substance to recognize fetal death occurring after the eighth week.⁵⁰

Retention of part or of the whole placenta after abortion or after premature or term labor causes persistence of the pregnancy reaction in blood and urine. The same applies to a placenta buried in the abdominal cavity after delivery of the fetus in abdominal pregnancy.⁵¹

In hydatid mole and chorionepithelioma the blood and urinary gonad stimulating factor reaches abnormally high levels. We have observed from 40,000 to 100,000 rat units per liter in the blood and urine. This is of clinical value, as Aschheim has pointed out.⁵² Incomplete removal, recurrences and metastases due to chorionepithelioma also can thus be diagnosed by persistence or recurrence of positive pregnancy tests in high dilution.

In hyperemesis gravidarum, Siebke⁵³ was unable to detect any abnormality in concentration of estrogenic substance in the blood.

53 Siebke, Harald. Ergebnisse von Mengenbestimmungen des Sexualhormons I. Mitteilung. Zentralbl f Gynak. 53:2450 (Sept 78) 1929.

In eclampsia, Anselmino and Hoffmann⁵⁴ report an increase of anterior pituitary-like gonadotropic factor in the blood, as well as of the antidiuretic factor of the hypophysis.

Fetus—Few observations are recorded. Brühl⁵⁵ found gonadotropic substance (reaction I) in the cord blood and urine of the neonatus of both sexes, disappearing within two days after birth.

We have found no estrogenic factor in the fetal blood, though Loewe⁵⁶ as well as Brühl⁵⁵ have reported its presence in the new-born of both sexes. Estrogenic substance is also found in the urine, disappearing within four days post partum. It is present in the amniotic fluid in considerable concentration, the amniotic fluid of cattle being used as the source for a commercial preparation (amniotin).

A Principle in the Female Having the Effects of the Testis Hormone—Traces of a bisexual "anlage," so manifest in certain vertebrates as the hen (left gonad, ovary, right, aplastic testis), may account for the constant presence in the urine of women of a substance having the effects of the testis hormone (Loewe,⁵⁷ Koch⁵⁸). Buhler⁵⁹ has found from 6 to 7 capon units daily in a hirsute female of the masculine type. No observations of any significant value have been made on patients with arrhenoblastoma—masculinizing tumor of the ovary.

MALES

Hormones—The testis hormone is demonstrable by several tests: by the capon's comb growth¹⁸ (capon unit), by the cytologic regeneration test⁶⁰ (mouse unit) and by the seminal vesicle and prostate cytologic test⁶¹ (rat unit).

The capon test, though time consuming, is more specific than the rat or mouse test. According to Moore and Gallagher,⁶¹ 1 rat unit equals 6 bird units.

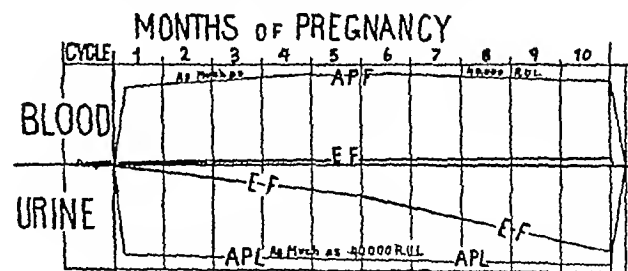

Chart 5—Stupendous increase of hormone production and excretion produced by pregnancy. Not to scale—the cyclic readings are exaggerated. The pregnancy curve is reduced.

The gonadotropic hormone of the adenohypophysis, as in the female, in the male governs not only pre-

puberal and puberal development but also sex function throughout adult life (Smith and Engle,⁶² Zondek²¹)

The same tests are employed for the gonadotropic factors as have been shown to be employed in the female. Estrogenic substance regularly is found in the urine and often in the blood of males. The Allen-Doisy test, previously referred to, is used.

Normal Male—No cycle has been demonstrated in the male.

Prepituitary Hormone No conclusive studies on the gonad stimulating factor in the blood and urine appear to be available. Katzman and Doisy²⁹ found that the adult male excreted about 4 to 19 mouse units daily of gonadotropic principle.

Testis Hormone In 1928 Loewe⁶³ demonstrated the excretion of testis hormone in the urine. In 1930 Womack and Koch⁶⁴ and simultaneously Loewe⁶⁵ found the testis hormone in the blood of bulls, the former found 1 capon unit to 600 cc, the latter one-half mouse unit per liter. Buhler⁶⁶ found the daily excretion of testis hormone at various ages to be from puberty to 20 years, 1 capon unit, from 20 to 30 years, 2 capon units, from 30 to 40 years, from 1 to 2 capon units, from 40 to 50 years, less than 1 capon unit, and 60 years and thereafter, 0.

Oesterreicher⁶⁶ demonstrated testis hormone in the urine of men up to the ninety-first year. Even in extreme age there was no increase of gonadotropic factor such as occurs after the menopause in women. Dingemans and his co-workers⁶⁷ regularly found from 2 to 8 capon units of testis hormone per liter in the urine of males.

Estrogenic Substance in the Male—Estrogenic factor has been found in the blood of normal males⁶⁸. Of forty-seven males, Goldberger and I⁶⁹ demonstrated it in three. It is a constant constituent of male urine. Laqueur⁶⁷ estimates the concentration as from 10 to 200 mouse units per liter.

Brahn⁷⁰ noted no quantitative difference in estrogenic substance in the urine of normal and of homosexual males.

Manifestations in Disease—Ferguson⁷¹ found the urinary excretion of gonadotropic factor greatly increased in malignant tumors of the testicle.

In 117 cases, from 50 to 40,000 mouse units per liter was obtained. The highest titers were noted in embryonal adenocarcinoma, the next lower were found in embryonal carcinoma with lymphoid stroma and the least was found in seminoma (from 400 to 2,000 mouse units per liter). Metastases increase the excretion. Ferguson obtained only follicle ripening (reaction I).

71 Ferguson R. S. Pathologic Physiology of Teratoma Testis. *J. A. M. A.* 101: 1933 (Dec 16) 1933.

In ten cases of seminoma, or other types of carcinoma, my associates and I found negative Friedman tests in all. In one case, after metastases developed, 1,000 rabbit units per liter (reaction III) was found in the urine.

Chorionepithelioma, arising from teratoma of the testis⁷² or ectopic, in the lungs,⁷³ gives a strong pregnancy reaction by either the Aschheim-Zondek or the Friedman test.

In my own five cases (to be published), all of which showed metastases when first observed, from 1,000 to 10,000 rabbit units per liter of anterior pituitary-like gonadotropic factor (reaction III, corpora lutea) was found in the urine. In one instance as little as 0.1 cc of urine gave a positive Friedman test. The amount of estrogenic substance in the urine varied from 25 to 250 mouse units per liter, the bloods all proved negative.

In a recent article, Geschickter and his co-workers⁷⁴ call attention to the high content of estrogenic substance in breast tumors and likewise imply that in gynecomastia of the male this abnormality must be ascribed to continuous increase of estrogenic or prepituitary-like factor.

SUMMARY

A. The bisexual gonadotropic hormone, which activates the ovaries and testes, has been demonstrated in the blood and urine.

1. Before puberty, small amounts of this hormone are noted in the blood and urine of children and adolescents. The hormone brings about the trophic growth of the genitals.

2. At puberty, greater amounts are demonstrable, causing full activation of the sex glands.

3. In the healthy adult female a cyclic activity of the prepituitary is manifested by the cyclic blood and urinary curve obtained.

4. After impregnation and throughout pregnancy an increase of from 100 to 200 times the amount found in the nonpregnant woman is noted in the blood and urine.

5. At the menopause the prepituitary cycle ceases. In one group (50 per cent) a permanent increase of a gonadotropic hormone is noted in the blood and urine, in the other group none is demonstrable. No clinical differences in these individuals are observed.

6. Functional diseases of the female genital tract appear due to disturbances of the prepituitary cycle. With present methods this cannot always be demonstrated by blood and urine hormone studies.

7. In the male there is no evidence of a prepituitary cycle or of a senile condition corresponding to the menopause.

B. The female and male sex glands produce distinctive hormones, which have been recovered from the blood and urine. A substance apparently identical with the testis hormone is found in the female, estrogenic substance is found in the male.

C. In the normal, mature, fertile woman, two hormones are secreted by the ovary.

1. The estrogenic factor, which circulates each month in increasing concentration in the blood stream until the onset of menstruation, with a typical urinary curve of excretion.

2 The progestational factor, as yet not demonstrated in the blood but found cyclically distributed in the urine

In pregnancy a higher level of the estrogenic factor is noted after the eighth week in the blood, and a disproportionately greater increase in the quantities excreted in the urine (placental effect)

D Normal genital function in the female is dependent on synchronism of prepituitary, estrogenic and progestational blood cycles (with corresponding, characteristic excretory curves)

Functional diseases, as has been shown by blood and urinary studies, are due to either underfunction or overfunction of the ovaries. The disturbances of function in most instances are primarily referable to disturbances of the prepituitary cycle

E The testis hormone has been demonstrated in the blood and urine. No cycle has been found, and little correlation between male functional diseases and changes in the humoral balance as yet has been discovered. Organic disease in the male can produce changes in the excretion of gonadotropic principle

10 East Eighty-Fifth Street

Council on Pharmacy and Chemistry

ANNUAL MEETING OF THE COUNCIL ON PHARMACY AND CHEMISTRY

The Council on Pharmacy and Chemistry of the American Medical Association held its annual meeting at the headquarters building, 535 North Dearborn Street, Chicago, Friday and Saturday, March 22 and 23, 1935. Those present were

Dr Stanhope Bayne-Jones	Dr Reid Hunt
Dr Kenneth D Blackfan	Dr Ernest E. Irons
Dr J Howard Brown	Dr Paul Nicholas Leech
Dr E M Bailey	Dr G W McCoy
Dr H N Cole	Dr E M Nelson
Dr Eugene F Du Bois	Dr W W Palmer
Dr C W Edmunds	Dr L G Rowntree
Dr Morris Fishbein	Prof W E Anderson of New Haven

Dr Reid Hunt was reelected chairman of the Council and Dr Torald Sollmann was reelected vice chairman

Among the many items discussed during the meeting, the following may be of interest both to physicians and to manufacturers

Shotgun Vitamin Therapy—The Council's clinical referee for vitamin preparations reviewed the present status of knowledge concerning the physiologic action of vitamin concentrates when administered in various combinations. It was brought out that there has been practically no experimental or clinical evidence which tends to show that the effect of vitamin concentrates are enhanced when these are given in combination. The best that could be expected from any given combination would be that each specific vitamin would produce its maximum effect independently of the other ingredients of the mixture and there are seldom conditions in which multiple avitaminosis exists

Evidence was reviewed which showed that the administration in combination of concentrates of vitamins each of which is active independently, may so alter the effectiveness of each as to render it inadequate or to necessitate an increase in its dosage. In view of this, it was pointed out that the attempt to supply a sufficient amount of a single vitamin concentrate specifically indicated, when a mixture of vitamins is prescribed, would result in an excess of the remaining active agents. The possibility of harm from such excess must be kept in mind, and, even when no harm is done such a combination may constitute

an economic waste. The clinical referee stated that there are some indications that the antiscorbutic effect of orange juice is diminished by addition of some preparations containing vitamins A and D (thus indicating that the cevitamic acid content is impaired) with the result that scurvy has been observed in children taking such combinations

It was brought out that there is an open field for the study of these questions, namely, incompatibilities, the possible impairment of vitamins when they are combined in mixtures containing a number of vitamins and extraneous material, and also the manner in which they are administered to the patient. Furthermore, it was pointed out that vitamins are rapidly entering the field of definite pharmaceuticals and may be considered as such—for instance, provitamin A (carotene), cevitamic acid (vitamin C) and the crystalline vitamin D type of preparation. A report on the status of vitamins is in the process of preparation

The Council voted not to accept combined concentrates of vitamins A, B and D until there is adequate evidence of the value of giving these vitamins in combination. The further action of the Council in the matter of vitamin mixtures will await the development of further evidence for or against this practice

Use of Antioxidants in Fish Liver Oil Preparations—The Council considered the practice of adding antioxidant agents, such as hydroquinone, to cod liver oil or halibut liver oil to prevent deterioration of vitamin A. The use of antioxidants is designed to delay the start of oxidation of vitamin A in oils having a short "induction period", that is, a short period before the fats begin rapidly to take up the oxygen of the air. Evidence is needed to show whether or not any by-product may be formed which might be toxic in the specific concentration of hydroquinone used. The possibility (which seems remote) of harm arising from continued use of hydroquinone must also be considered. Under ordinary conditions of use, however, there appears to be no necessity for the addition of an antioxidant to cod liver oil or halibut liver oil

The Council voted that manufacturers of accepted products be informed that under conditions of ordinary usage there does not appear to be necessity for use of hydroquinone for the proper preservation of cod and halibut liver oil and that until more convincing evidence in favor of the practice is submitted, it may not be permitted

Differences in Antirachitic Effects of Fish Liver Oils of Different Species—The Council considered a review of the article of Bills (*Physiol Rev* 15 1 [Jan.] 1935) showing, on the basis of comparative assays on rats and chickens, that there is an apparent difference between qualitative and quantitative relation of antirachitic effect of fish liver oils of different species. The Council postponed consideration of the bearing of the question on the fish liver oils for use by man. It was brought out that the question could be settled only by adequate comparative clinical tests

Lay Advertising of Vitamin Preparations—At its annual meeting in 1934, the Council decided not to countenance the advertising to the public of halibut liver oil, halibut liver oil with viosterol and viosterol in oil, because the high potency of these preparations renders them unsuitable for lay use without medical supervision. The Council sanctions proper advertising to the public of cod liver oil for prophylactic use. Attention was called to the fact that certain firms which market accepted halibut liver oils were not observing the Council's restriction as to lay advertising. After due consideration the Council reaffirmed its attitude as to lay advertising of halibut liver oil and directed that attention of firms be called to any disregard of the Council's rules by advertising of halibut liver oils to the public

Permissible Claims for Vitamin A—The Council has defined its attitude toward the permissible claims for vitamin A by the statement in *Hospital Practice for Interns*, page 78, under "Oleum Morrhuæ": "By virtue of its vitamin A content it promotes growth and, as indicated by experimental studies, may be an aid toward the establishment of resistance of the body

to infection in general, though it has not been shown to be specific in the prevention of colds, influenza and other such infections." There was recently brought to the Council's attention a summary of medical literature which, it was contended, contained evidence that vitamin A may be of value in reducing the incidence of the common cold. The Council's referee and a colleague reviewed this evidence and the referee presented the review to the Council. In the light of this review, it was agreed that there is not acceptable evidence to warrant the Council in countenancing the claim of anti-infective activity for vitamin A preparations. The Council voted that the permissible claims for vitamin A remain in statu quo, namely as defined in the quotation from Hospital Practice for Interns given at the beginning of this paragraph. In addition, it was the understanding that recommendations for the administration of vitamin A to aid in building general resistance should be made only in cases in which the lack of resistance is due to deficiencies of this vitamin.

Liver Preparations—The Council recently sent to manufacturers of accepted liver preparations new proposed standards for determining and expressing the potency of these products. These standards have been worked out in cooperation with the Pharmacopoeial Revision Committee which is considering the same subject. The Council's referee reported on the replies of some firms giving certain objections that had been raised. Prof. E. Fullerton Cook, Chairman of the U. S. P. Revision Committee, participated in the discussion of this topic. Professor Cook reported on the progress being made by the Pharmacopoeial Committee. The Council postponed final action in order to consider the matter of various suggestions made for revision of the proposed standards.

Antipneumococcus Serums—It has been brought to the attention of the Council that a pharmaceutical house is marketing an antipneumococcus serum with the claim that the product contains certain heterophile units' and neutralizing agents representing advantages over ordinary products of this class. The firm has not presented the product for inclusion in New and Nonofficial Remedies.

After some discussion, the Council voted that the firm in question be invited to present the available evidence in order that the Council may consider it and report to the profession on the status of such a product in the light of the evidence for the claims made.

Scarlet Fever Preparations in Bulk Packages—It has been brought to the attention of the Council that the marketing of scarlet fever preparations in bulk packages increases the likelihood of contamination and loss of potency. In the discussion of this question, it was pointed out that the Council has already indicated the hazards of using multiple dose containers and has repeated the warning in its report on the sterility of ampules (THE JOURNAL, Sept. 1, 1934, p. 678). The Council decided that further action in this matter should be left to the Scarlet Fever Committee, Inc., and the manufacturers concerned.

Status of the Articles on Glandular Physiology and Therapy—The Council authorized the preparation of this series of articles at its annual meeting in 1934. It was reported to the Council that the series, which is currently appearing in THE JOURNAL, is attracting wide attention. The Council authorized preparation of an additional article dealing with the status of commercial glandular products.

The Council's Rules—The Council discussed various proposed revisions and interpretations of the rules. It was decided that a compilation should be made of the various general affirmative actions or decisions of the Council and that these shall be published for the information of the manufacturers and others.

Bacillus Acidophilus Preparations—The Council has continued its consideration of bacillus acidophilus preparations with the view to determining their proper status. In the discussion it was pointed out that there remain in the accepted list only four or five brands of bacillus acidophilus milk and one concentrate. Advertising has been restricted to very modest claims. The Council recently reaccepted most of the milk preparations for a period of three years. It was agreed that a period of approxi-

mately five years will be needed for definitive study of the worth of the milk preparations with special attention to dosage. It was pointed out that all the work up to this date has been done with milk preparations and that claims have been made for concentrates of bacillus acidophilus on the strength of these studies. Evidence is needed that is based on results with the concentrates themselves, especially since these do not seem to retain viability for as long a time even as the milk preparations. It should be pointed out that the reduction in the number of accepted products has been caused mainly by failure of the omitted products to show, as a result of bacteriologic examination, the number of viable organisms per unit volume prescribed by the Council for accepted products.

Use of the Term "Obstetrical" on Labels of Pituitary Liquid—Attention was called to the practice of certain firms marketing accepted brands of solution of pituitary of including the bracketed term "Obstetrical" in the name.

The Council directed that the name "Pituitary Solution (Obstetrical)" be not recognized but that manufacturers of accepted brands of pituitary solution be informed that the Council will not object to the use of the phrase "for obstetrical use" underneath the name or elsewhere on the ampule label.

Commercial Reprints of Council Reports—The Council has at times considered the desirability of extending to commercial firms the privilege of using Council reports in the promotion of their accepted products. It was decided that the Council would not grant permission for such use of its reports.

Sterility of Catgut Sutures—The Council considered the question of sterility of catgut sutures. After considerable discussion, it was agreed that the Council should undertake a limited examination of samples of catgut on the market. The Council therefore voted to bring to the attention of the Board of Trustees the necessity for examination of catgut and to ask the Board for authorization of such an investigation under the direction of the Council's Committee on Serums and Vaccines. The Board was asked to consider the relationship between the work of the Council's committee and that of the Committee on Catgut Standards previously appointed at the instigation of the Section on Surgery of the Scientific Assembly. [The Board of Trustees has since made an appropriation and has given the Council the desired authorization.]

Advertising for Aminophyllin—The Council discussed the difficulty in determining the exact clinical status of Aminophyllin. It felt that some advertising claims for the product carried overoptimistic implications.

Dimitrophenol—The Council has already issued a preliminary report on this drug (THE JOURNAL, July 15, 1933, p. 210). It is still considering the drug but is not yet prepared to accept it for inclusion in New and Nonofficial Remedies, its therapeutic indications and limitations not being established although its toxicity is definitely understood. The Council decided that a progress report on the drug is necessary and instructed the referee to submit such a report in the near future with view to its publication.

Fantastic Claims—The Council definitely disapproved the use of fantastic statements and slogans offered in the advertising of certain accepted products. The Council directed that a general decision on similar vague health claims be prepared for adoption and later publication.

Reports of Committees—The Committees on Useful Drugs, New and Nonofficial Remedies, Hospital Practice for Interns, and Epitome of the Pharmacopeia and National Formulary reported that revision of these texts will be necessary in the coming year to bring them into harmony with the new Pharmacopeia and the new National Formulary. The committees asked for suggestions as to additional revisions which Council members might deem necessary.

The Committee on Therapeutic Research reported that it would continue to follow the same policy as formerly in making grants in aid of research, namely, a sum generally between one hundred and two hundred fifty dollars for the purchase of materials or special apparatus.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS COMFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

IPRAL SODIUM—Sodium ethylisopropylbarbiturate—
 $\text{NaC}_2\text{H}_5\text{C}_3\text{H}_7\text{CCONHCO NCO}$ The sodium salt of ethylisopropylmalonyl urea

Actions and Uses—Ipral sodium has the therapeutic properties of barbituric acid. It is soluble in water and is absorbed promptly. It is claimed that it is excreted rapidly, but some action commonly persists for twenty-four hours. In therapeutic doses it affects the higher cerebral centers almost exclusively, and such doses exert no perceptible effect on the heart or circulation directly.

Ipral sodium is used as a hypnotic to combat restlessness, irritability and sleeplessness. It is claimed that tolerance to ipral sodium is not developed readily, and that its action is persistent.

Dosage—From 0.12 to 0.25 Gm (2 to 4 grains) followed by a cupful of hot water, tea or milk.

Manufactured by E. R. Squibb & Sons, New York. U. S. patents 1,255,951 (Feb. 12, 1918, expires 1935) and 1,576,014 (March 9, 1926, expires 1943). U. S. trademark 208,813.

Ipral Sodium Tablets 4 grains

Caution—Aqueous solutions of ipral sodium are not stable but decompose on standing on boiling a precipitation occurs.

Ipral sodium is a white hygroscopic powder, soluble in water, slightly soluble in alcohol and practically insoluble in ether and chloroform. An aqueous solution of ipral sodium has an alkaline reaction to litmus.

Dissolve about 0.5 Gm of ipral sodium in 100 cc of water, add an excess of diluted hydrochloric acid, collect the resultant ethylisopropylbarbituric acid on a filter, wash and dry at 100°C. it melts at 200-205°C. Incinerate about 1 Gm. of ipral sodium, the residue responds to tests for sodium carbonate. Boil about 0.5 Gm of ipral sodium with 5 cc. of a 25 per cent sodium hydroxide solution, it is decomposed with evolution of ammonia. Dissolve about 0.3 Gm of ipral sodium in 10 cc of water and divide into two portions; to one portion add 1 cc of mercuric chloride solution, a white precipitate results, soluble in an excess of ammonia; to the other portion add 5 cc of silver nitrate solution, a white precipitate results, soluble in an excess of ammonia.

Dissolve about 0.5 Gm of ipral sodium in 50 cc of water, add 5 cc of diluted nitric acid and filter through paper. Separate portions of 10 cc each of the filtrate, yield no opalescence on the addition of 1 cc of silver nitrate solution (chloride), no turbidity on the addition of 1 cc of barium nitrate solution (sulphate). To about 0.2 Gm of ipral sodium in 25 cc of water, add 1 cc of diluted hydrochloric acid, filter through paper, the filtrate yields no coloration or precipitation on saturation with hydrogen sulphide (salts of heavy metals). Add about 0.1 Gm of ipral sodium to 1 cc of sulphuric acid, the solution is colorless (readily carbonizable substances).

Transfer about 1 Gm. of ipral sodium, accurately weighed to a glass stoppered cylinder, add 50 cc of anhydrous ether, stopper and shake for ten minutes, decant the supernatant liquid through filter paper and repeat twice using 25 cc and 15 cc portions respectively of ether, utilizing the same filter, evaporate the combined filtrates to dryness in a tared beaker and dry to constant weight at 90°C, the residue does not exceed 0.2 per cent (uncombined ethylisopropylbarbituric acid).

Dry about 1 Gm of ipral sodium, accurately weighed to constant weight at 100°C, the loss does not exceed 2 per cent. Transfer about 0.5 Gm of ipral sodium, accurately weighed to a suitable Squibb separatory funnel, add 50 cc of water, followed by addition of 10 cc of diluted hydrochloric acid, extract with eight successive portions of ether, 25 cc each, evaporate the combined ethereal extractions to dryness in a stream of warm air and dry to constant weight at 100°C, the amount of ethylisopropylbarbituric acid corresponds to not less than 88.5 per cent nor more than 90.5 per cent, calculated to the dried substance. Transfer the acidulated aqueous portion from the foregoing immiscible solvent extraction to a tared platinum dish and evaporate to dryness on a steam bath, to the residue obtained, add 5 cc of sulphuric acid, heat cautiously until the excess of sulphuric acid has been volatilized, repeat twice using portions of 1 cc each of sulphuric acid each time, add about 0.5 Gm of ammonium carbonate, ignite to constant weight and weigh as sodium sulphate, the percentage of sodium corresponds to not less than 9.5 per cent nor more than 12.5 per cent when calculated to the dried substance.

DIPHThERIA TOXOID, ALUM PRECIPITATED (REFINED) (See New and Nonofficial Remedies, 1935 p 394)

Wm S Merrell Co, Cincinnati

Diphtheria Toxoid Alum Precipitated (Refined) (See THE JOURNAL Dec 22, 1934 p 1947).—Also marketed in packages of ten 1 cc vials (ten immunizations).

METYECAINE (See New and Nonofficial Remedies 1934 p 54)

The following additional dosage form has been accepted

Metycaine Tablets 15 grain

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING APPROVED RULE

RAYMOND HERTWIG Secretary

VIOLATION OF RULES

Acceptance of a product may be withdrawn if the spirit or meaning of these rules should be violated.

No food product or class of food products, or advertising therefor, will be accepted, or if accepted will be retained, if in the opinion of the Committee such acceptance is likely to be construed as an acceptance or approval of any other products or activities of a firm, when such other products or activities of such firm are in conflict with the policies of the American Medical Association as set forth in the rules of the Committee on Foods, or those of the Council on Pharmacy and Chemistry or of the Council on Physical Therapy.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

WARRANTY SIEVED TOMATOES

Manufacturer—The Nielsen Corporation, Ltd, Oakland Calif

Description—Sieved tomatoes prepared by efficient methods for retention in high degree of the natural mineral and vitamin values. No added sugar or salt.

Manufacture—Fresh tomatoes are washed, sorted, trimmed of all objectionable material, again washed, crushed, heated to the boiling point and delivered to a pulping machine and finisher, where the seeds, skins and cores are removed. The pulp is concentrated in a vacuum pan at a temperature of 63°C to the desired consistency, filled into cans and processed as described for Warranty Sieved Spinach (THE JOURNAL Feb 2, 1935 p 399).

Analysis (submitted by manufacturer) —

	per cent
Moisture	91.6
Total solids	8.4
Ash	0.7
Sodium chloride	0.1
Fat (ether extract)	0.1
Protein (N X 6.25)	1.2

Carbohydrates other than crude fiber (by difference)	5.6
Titratable acidity as citric acid	0.5

Calories—0.3 per gram 9 per ounce

Instructions—The method of preparation and processing insures the retention in high degree of the natural vitamin values.

Claims of Manufacturer—Specially intended for infants, children and convalescents, and for special smooth diets. Only warming is required for serving.

COFFEE FLAVOR SPARKLE GELATIN DESSERT

Manufacturer—Quaker Maid Company, New York.

Description—Gelatin dessert powder containing sucrose, gelatin, coffee extract and sodium chloride.

Manufacture—The ingredients in formula proportions are automatically mixed, dried, and packed in cartons.

Analysis (submitted by manufacturer) —

	per cent

SATURDAY, JUNE 1, 1935

DEFINITION OF ALLERGIC DISEASES

The development of the term "allergy" and the rapid increase in knowledge concerning this state have resulted in widespread loose usage. An allergic state has thus been proposed as the explanatory mechanism in a vast number of diseases both common and rare. Perhaps it is time now to examine the definition and determine its present status.

Rackemann¹ quotes Pirquet as defining allergy as a changed reaction capacity that the human or animal organism gains through recovery from disease or through treatment with foreign substances. Later Rackemann states that "allergy is the capacity to react to many substances which are entirely innocuous to normal individuals." Tuberculosis, for example, could scarcely be classed as an allergic disease under this definition. In discussing the same subject, Vaughan² says "The word allergy is derived from the Greek and means altered energy or altered activity, or altered reactivity. The allergic individual reacts differently to certain stimuli with which he comes in contact. What is harmless for the nonallergic person causes severe symptoms in the allergic patient." This definition allows considerable leeway in interpretation. Although arising largely from a study of anaphylactic phenomena in animals, the conception of allergy as altered reactivity of the body might be stretched to cover almost any deviation from functional normality. While perhaps strictly permissible, this broad interpretation departs widely from the meaning of the term at the time of its introduction.

From time to time there have been investigators who uttered feeble protests at the all embracing progress of allergy, but these have been engulfed by animal experiments showing that almost any type of inflammatory lesion can be produced by protein sensitization. Suggestive evidence such as Key's³ experiments, which

showed similar inflammatory lesions in animals from nonprotein chemicals, have been met by postulating a combination of these chemicals with human blood protein to make a new protein that behaves like a foreign one⁴. Although possibly true, the burden of proof of the latter view necessarily rests with those who propose it.

Aschoff⁵ has recently lent his weight toward a relatively narrow definition of allergic diseases. He believes that allergy should be restricted to disorders that appear in attacks on the basis of a true tissue hypersensitivity. The transference of observations on artificial allergy in animals to human subjects he deprecates. This process has gone so far that allergic manifestations occurring in the course of infectious diseases are interpreted as meaning that the disease is itself allergic. A disturbing confusion has thus resulted in that etiologically different even if symptomatologically similar disturbances are designated as allergic because certain local histologic changes resemble the allergic inflammations that are produced artificially in animals. Aschoff objects to such disregard of specific pathogenic and pathologic laws. The tendency to assign the rheumatic state, for example, to a common allergenic agent is, he believes, a step backward. The grouping together of etiologically different diseases merely because of similar symptomatology or supposed common protein sensitivity is essentially unsound. Only a sharp etiologic differentiation makes effective causal therapy possible.

Whatever the ultimate outcome, it must be granted that much present use of the term "allergy" does not lend itself to clear thinking. The convenience of its use to explain processes not well understood recalls earlier use of such expressions as "ptomaine poisoning" or "intestinal flu." In the main it would probably be well to restrict the term to those disorders of sudden onset in which a specific tissue hypersensitivity is demonstrable. Pending the results of further investigation, allergy should be used sparingly in relation to the majority of inflammatory diseases.

HUMAN STERILIZATION

Legislation affecting human sterilization has been or is being considered in the 1935 sessions of ten state legislatures. Already such legislation is presumably effective in many other states. The medical profession is frequently called on to present its views on the present status of knowledge of human inheritance and the indications for and limitations of human sterilization.

The inheritability of human structural and mental characteristics is not as easily determined as is that of animals, since the latter can usually be studied according to known laws of genetics. There is a body of opinion which believes that human inheritance cannot be determined. There are others who maintain that

⁴ Vaughan. *Allergy and Applied Immunology*, p. 76.

⁵ Aschoff, Ludwig. "Ueber den Begriff der allergischen Krankheiten." *Med. Klin.* 31: 1 (Jan. 4) 1935.

much positive evidence is obtainable. Although at present the public interest is focused on mental defects, some of the best evidence of human inheritance lies in the field of developmental structural abnormalities. Some such physical defects appear to be pure dominant, some recessive and some sex linked. The same defect may be, for example, dominant in one family and sex linked in another. The mechanism in hemophilia, for example, is incontrovertible. Recently Macklin¹ has said that developmental defects, like developmental normalities, are hereditary.

There are several factors that make mental defects more difficult to follow. Mental defect grades from normal to abnormal without any sharp dividing line. Furthermore, moderate mental deficiency in families is often overlooked in the pedigree method of studying inheritance. In spite of these difficulties, data are obtainable that indicate beyond reasonable doubt the inheritance of certain mental characteristics. Macklin has pointed out the advantages and disadvantages of methods of study of human genetics. For example, the incidence of consanguineous marriages among the parents of persons showing a supposedly inherited trait may give information not only as to the inheritability but also as to the type of heredity exemplified in the trait in question. Similarly the same defect or disease occurring in identical twins in excess of the expected ratio for the general population would indicate a hereditary basis. Finally, Macklin believes that much important information is obtainable from a study of the frequency in related as compared with that in unrelated persons. Somewhat similar conclusions are pointed out by Roberts,² by the Brock³ report in Great Britain and by others.

There is sufficient evidence of the inheritability of certain structural and mental defects, but control measures should be definitely limited to those defects whose essential inheritability and mode of transmission are known. The established genetic foundation must not be exceeded. Although compulsion serves as the basis for most state legal enactments in this country, mandatory action has been criticized by Myerson⁴ and in the Brock report in view of the inherent danger in sterilization laws that might become punitive. Voluntary sterilization, limited to individuals possessing strong potentialities for perpetuating individually or socially serious physical or mental traits, is a rational procedure. The Brock report, however, raises at least two objections to a scheme for voluntary sterilization. It is argued that, if really voluntary, consent will not be obtained, also that defectives are so suggestible that they will be too readily persuaded and hence their consent is really meaningless. From a practical standpoint,

the Brock committee does not consider either objection valid, for, with reasonable eugenic knowledge and intellectual honesty among those responsible for proposing sterilization, these objections should be immaterial.

"BAIT ADVERTISING" UNLAWFUL

The Constitution of the United States does not grant to any physician or dentist the right to use so-called bait advertising to lure patients into his office and to trap them into agreements which otherwise they would not make. It is no defense to say that the advertising is truthful or that in a particular case it was not resorted to for an improper purpose. If any legislature forbids through legislation all such advertising by members of any particular profession without regard to its truthfulness or purpose in particular cases, it is not for the courts to challenge that judgment. This is the gist of the decision recently rendered by the United States Supreme Court in *Semler v. Oregon State Board of Dental Examiners* (55 Sup. Ct. 570).

The case arose under a statute enacted by the Oregon legislature in 1933 (Oregon Laws, 1933, chapter 166), enlarging the list of causes for which licenses to practice dentistry might be revoked. It authorized the revocation of such a license if the licensee should be guilty of "advertising professional superiority or the performance of professional services in a superior manner, advertising prices for professional service, advertising by means of large display, glaring light signs, or containing as a part thereof the representation of a tooth, teeth, bridge work or any portion of the human head, employing or making use of advertising solicitors or free publicity press agents, or advertising any free dental work, or free examination, or advertising to guarantee any dental service, or to perform any dental operation painlessly." Semler, a dentist practicing in Portland, Ore., sought an injunction to prevent the enforcement of the act. His petition having been denied by the circuit court and by the Supreme Court of Oregon, he appealed to the Supreme Court of the United States. He contended that the statute was unconstitutional in that it denied due process of law and equal protection of the law and impaired the obligation of contracts. The United States Supreme Court, however, rejected this contention, saying as it did so:

We do not doubt the authority of the state to estimate the baleful effects of such methods and to put a stop to them. The legislature was not dealing with traders in commodities, but with the vital interest of public health, and with a profession treating bodily ills and demanding different standards of conduct from those which are traditional in the competition of the market place. The community is concerned with the maintenance of professional standards which will insure not only competency in individual practitioners, but protection against those who would prey upon a public peculiarly susceptible to imposition through alluring promises of physical relief. And the community is concerned in providing safeguards not only against deception, but against practices which would tend to demoralize the profession by forcing its members into an

unseemly rivalry which would enlarge the opportunities of the least scrupulous. What is generally called the "ethics" of the profession is but the consensus of expert opinion as to the necessity of such standards.

It is no answer to say as regards appellant's claim of right to advertise his "professional superiority" or his "performance of professional services in a superior manner," that he is telling the truth. In framing its policy the legislature was not bound to provide for determinations of the relative proficiency of particular practitioners. The legislature was entitled to consider the general effects of the practices which it described and if these effects were injurious in facilitating unwarranted and misleading claims, to counteract them by a general rule even though in particular instances there might be no actual deception or misstatement.

While this decision has reference only to the Oregon law, it will protect from attack on the basis of supposed invalidity under the federal constitution the many similar laws¹ for the regulation of advertising by dentists that have been enacted during the last few years. Indeed, the dental profession seems to have concentrated its efforts toward modernizing the dental practice acts of many states and in doing so it has incorporated in them provisions looking toward the better regulation of dental advertising. The success of their efforts, which so far as advertising is concerned seems to be assured by the decision of the United States Supreme Court, should encourage the medical profession to seek similar legislation where present advertising privileges are abused.

BLOOD GROUPING TESTS AND THE LAW

At the meeting of the Session on Forensic Medicine of the Section on Miscellaneous Topics at the annual session of the American Medical Association in Cleveland last June, a motion was passed¹ to "organize a committee for the purpose of acquainting the suitable authorities in the legal profession with the existence and reliability of the blood grouping tests, so that

1 During 1933, 1934 and to date in 1935 the following states have adopted amendments to their laws regulating the practice of dentistry substantially similar with respect to advertising prohibitions to the Oregon law.

1933
Delaware Laws 1933 c. 240
Illinois Laws 1933 p. 708
Maryland Laws 1933 c. 564
Wisconsin Laws 1933 c. 189

1934
Massachusetts Laws 1934 c. 281
Rhode Island Laws 1934 c. — approved May 4 introduced as H 835

1935
California Laws 1935, c. 147
Colorado Laws 1935 c. — approved March 8 introduced as S 329
Idaho Laws 1935 c. — approved March 5 introduced as H 85
Indiana Laws, 1935 c. — approved February 26 introduced as H 218
Iowa Laws 1935 c. — approved May 6 introduced as H 203
Maine Laws 1935 c. 97
Montana Laws 1935 c. — approved February 23 introduced as H 87
Nebraska Laws 1935 c. — approved May 13 introduced as S 100
New Hampshire Laws 1935 c. — approved February 26 introduced as H 134
Tennessee, Laws 1935 c. 126
Utah Laws 1935 c. — approved March 22 introduced as S 9

The Indiana amendment appears to impose even more stringent prohibitions with respect to advertising than does the Oregon law.

1 Communication from the Session on Forensic Medicine of the Section on Miscellaneous Topics. Minutes of the House of Delegates J. A. M. A. 102:2205 (June 30) 1934. Section on Miscellaneous Topics. Session on Forensic Medicine. Minutes of the Sections. *ibid.* 103:46 (July 7) 1934.

statutes may be enacted authorizing courts to order individuals to submit to blood grouping tests when they are required, in those jurisdictions in which blood tests are not obligatory at present." The first step toward this goal was taken recently in New York State, when blood grouping bills that had passed the legislature were signed by the governor.² Only a short time previously a case of disputed paternity had come before the supreme court of that state, in which blood tests were ordered by Justice Meier Steinbrink at the request of the defendant. The plaintiff refused to submit to the tests and on appeal to the appellate division of the supreme court, Justice Steinbrink's decision was reversed, since it was held that there was no statutory authority for such an order.³ However, the new legislation will give this authority to judges trying future cases in New York State. A brief summary of the major forensic applications of blood grouping may be of interest at this time.⁴ In illegitimacy proceedings, the tests can be used to exclude but not to prove paternity. Thus, if the mother belongs to group A, the child to group B and the supposed father to group A, the accused man could not be the father of the child, since the child possesses an agglutinin B which neither of the supposed parents has. On the other hand, if the accused man is found to belong to group B, this would not prove him to be the father of the group B child, since 15 per cent of all men belong to this group and there is a possibility of coincidence. With the aid of the four classic Landsteiner blood groups, one sixth of all falsely accused men can be exonerated. The agglutinogens M and N, discovered by Landsteiner and Levine⁵ in 1928, have doubled the number of cases in which an exclusion can be obtained, so that now one out of three falsely accused men can be exonerated. In criminal cases the blood grouping tests are useful for purposes of identification. They are of great value in such cases, since at the present time as many as eighteen distinct types of human blood can readily be differentiated. For example, suppose that a criminal is wounded in a chase by the police but escapes. Some of his blood left at the scene of the crime is found to belong to group A, type N. All suspects except those belonging to this type can immediately be eliminated, and thus much time and expense can be saved. The value of keeping records of each criminal's blood group as well as his finger prints should therefore be evident. Incidentally, though clever surgeons with shady reputations have devised methods of altering the finger prints of criminals, it is impossible to change the blood group. The tests for M and N and the tests on old blood stains are of an exceedingly delicate nature and should be entrusted only to properly qualified individuals. This is important, since errors in diagnosis might result in grave injustice.

2 Time 25:66 (April 1) 1935.

Association News

THE ATLANTIC CITY SESSION

Scientific Exhibit

The attention of those attending the Atlantic City session is called to the fact that the Scientific Exhibit is not open evenings. The hours on Monday, June 10, will be from 12 noon until 6 p. m. and on other days from 8 30 a. m. until 6 p. m., except Friday, June 14, when the Scientific Exhibit closes at 12 noon.

Admission to the Scientific Exhibit is limited to individuals wearing Fellowship badges or other badges of the convention and to guests to whom special cards of admission have been issued. The public is not admitted to the Scientific Exhibit.

Fraternity and Club Luncheons

Theta Kappa Psi Medical Fraternity will hold a luncheon Wednesday, June 12, at 12 30 p. m. at the Madison Hotel, Atlantic City.

The Phi Rho Sigma Luncheon will be held Wednesday, June 12, at the Ambassador Hotel in Atlantic City, 12 30 p. m.

Details on the Phi Beta Pi Medical Fraternity luncheon may be obtained from the Phi Beta Pi booth at the Atlantic City session.

Meeting of the American Radium Society

The American Radium Society will hold its annual meeting in the Vernon Room of Haddon Hall, June 10-11. Symposia on radium packs, biopsies and breast cancer will form a large part of the program. The session, Tuesday afternoon, however, will be devoted to miscellaneous problems.

Radio Broadcasts from Atlantic City and Philadelphia

Through the courtesy of the National Broadcasting Company and the Columbia Broadcasting System the American Medical Association will broadcast health talks to the public in connection with the annual meeting at Atlantic City, June 10 to 14.

The talks over a network of the National Broadcasting Company will originate in the studios of Station WFIL at Philadelphia according to the following schedule (eastern daylight saving time):

- June 11 5-5 15 p. m. The Polio Situation by Dr. J. P. Leake
- June 12 Hour to be announced. News Features from the Convention. W. W. Bauer, M.D.
- June 14 5-5 30 p. m. Medicine in North America. Nutrition and the Health of the Race by Dr. James S. McEster. Truth in Therapeutics by Dr. Jonathan C. Meakins. Speakers to be introduced by Dr. Morris Fishbein.

The talks over a network of the Columbia Broadcasting System will originate in the studios of Station WPG, Atlantic City according to the following schedule:

- June 10 5-5 15 p. m. Sidelights on Sleep by Dr. Cleveland Giddings, Jr.
- June 14 3 15-1 30 p. m. Problems of the Hard of Hearing by Dr. Austin A. Hayden.

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45 Chicago daylight saving time (3 30 central standard time). The next three broadcasts will be as follows:

- June 6 Wound Infections. W. W. Bauer, M.D.
- June 13 Summer Camps. C. C. Bean.
- June 20 Burns. W. W. Bauer, M.D.

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4 15 Chicago daylight saving time (3 o'clock central standard time). The next three broadcasts will be as follows:

- June 4 The Crippled Child. W. W. Bauer, M.D.
- June 11 See announcement of broadcasts from annual session.
- June 18 Only One Pair of Eyes. W. W. Bauer, M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

State Medical Election—Dr. Charles A. Thigpen, Montgomery, was chosen president of the Medical Association of Alabama at its annual meeting, April 18. Dr. Charles P. Hayes, Elba, was named vice president of the southeastern division. Montgomery was designated as the place for the next annual meeting, April 21-23, 1936. At this session Dr. James N. Baker, Montgomery, was unanimously reelected state health officer for a second five year term, and a resolution was adopted urging the legislature to increase the state health officer's salary to a sum "commensurate with the office."

Changes in Health Officers—Dr. Leslie G. Cole has been appointed in charge of the Bullock County Health Department, succeeding Dr. Ernest G. Moore, Union Springs, who recently resigned to engage in private practice in Tallahassee. Dr. Marion L. Shaddix, Phenix City, has been named health officer of Russell County. Dr. Lee Weathington, Boaz, has been appointed health officer of Marshall County. Dr. Hugh C. Nickson has recently been appointed health officer of Chilton County at the head of a new full time health unit. Dr. Myrtus R. McWhorter, Woodland, has been appointed full time health officer of Randolph County, with headquarters in Wedowee.

ARKANSAS

Personal—Dr. James D. Mooney has been elected mayor of Coal Hill. Dr. James T. Powell has been appointed health officer of Gravette and Dr. J. Pell Baker of West Helena.

Society News—Speakers before the Pulaski County Medical Society, Little Rock, recently, were Drs. Louis Hamman, Baltimore, and Douglas Quick, New York, on heart pains and irradiation of cancer, respectively. The Physicians' Business and Credit Rating Bureau of Jonesboro has been organized with Dr. Ralph M. Sloan as president. At a meeting of the Academy of Medicine of Hot Springs National Park, April 2, Drs. Neil D. Buie and Thomas G. Glass, Marlin, Texas, discussed hypertension.

CALIFORNIA

Dr. Wilbur Made President of Motion Picture Council—Dr. Ray Lyman Wilbur, president of Stanford University and former Secretary of the Interior, has been elected president of the Motion Picture Research Council. This council was formed in 1928 to promote studies of the social value of motion pictures and to apply its conclusions to improving the movies.

Changes in Health Officers—The following physicians have recently been appointed health officers:

Oscar J. Hansen, Redding, of Shasta County, succeeding Dr. Benjamin F. Taylor.
Oran Newton Taft to succeed the late Dr. Perryman F. Page, Jr.
William T. Heffernan of Calexico to succeed Dr. Frederick C. Gregg.
John A. Wallace of Calipatria to succeed Dr. John H. Hutton.

Society News—The urologic section of the Los Angeles County Medical Society arranged a symposium on renal infections exclusive of tuberculosis for the meeting April 18. It was presented by Drs. Hermon C. Bumpus, Pasadena; William H. Leake, Arthur Elmer Belt, George F. Schenck, Verne R. Mason and Robert V. Day. Drs. Pierre P. Viole and Carl W. Rand addressed a joint meeting of the Los Angeles Society of Ophthalmology and Otolaryngology and the Los Angeles Society for Neurology and Psychiatry, April 25, on "Clinical and Post-mortem Conclusions Concerning the Intracranial Complications of Acute and Chronic Paranasal Sinus Disease and Visual Field Alterations Following Craniocerebral Injuries respectively." Dr. John B. deC. M. Saunders, San Francisco, discussed "Development of the Spinal Column and Its Relationship to Certain Injuries before the Hollywood Academy of Medicine, May 16."

COLORADO

Annual Surgical Clinics—The first annual surgical clinics under the auspices of the Kit Carson County Medical Society were held at the Cheyenne County Hospital, April 1-2, with Dr. Leonard N. Myers, Cheyenne Wells, as host. The session opened with clinics for appendectomy, inguinal hernia and hysterectomy. Following a luncheon, Dr. Judson D. Moschelle, Indianapolis, guest clinician, conducted a clinic and lectured on

thyroidectomy. Dr Myers entertained in the evening with a dinner and smoker. The following morning was devoted to clinics.

DISTRICT OF COLUMBIA

Personal—Dr Edward J Schwartz resigned as assistant health officer of the District of Columbia, April 1.

Society News—Speakers before the Medical Society of the District of Columbia, April 24, included Drs George L Weller Jr on 'Early Clinical Recognition of Adrenal Insufficiency Resulting from Partial or Total Atrophy of the Adrenal Glands', James Alexander Lyon, 'Dissociation of the Thyroid from the Sympathetic Nervous System and Reduction of the Blood Supply to the Thyroid in the Treatment of Angina Pectoris,' and Harry S Bernton, 'The Hygiene of Hay Fever.'

FLORIDA

Society News—Dr Paul B Welch discussed 'A Comparison of Disease Incidence in Iowa and Florida with Special Reference to the Effect of Climate upon the Incidence of Digestive Disease' before the Dade County Medical Society in Miami, April 5, and Dr Harry Hamilton Cooke 'Skull Injuries.'

State Medical Election—Dr Orion O Feaster, St Petersburg was chosen president-elect of the Florida Medical Association at its annual meeting in Ocala, May 15 and Dr Herbert L Bryans, Pensacola, was inducted into the presidency. Other officers of the association are Drs Eugene G Peck, Ocala, John W Alsobrook, Plant City and J Turberville, Century, vice presidents and Dr Shaler A Richardson Jacksonville who was reelected secretary. It was decided to hold the convention in 1936 aboard the S S Florida on a cruise among the Bahama Islands, newspapers reported.

GEORGIA

University News—Dr Eliot R Clark professor of anatomy, University of Pennsylvania School of Medicine Philadelphia, addressed a joint meeting of the University of Georgia Science Club and the Louis Dugas Journal Club of the University in Augusta, April 15, on the vascular system.

State Medical Election—Dr Benjamin H Minchew, Waycross, was chosen president-elect of the Medical Association of Georgia at its annual meeting in Atlanta May 10, and Dr James E Paulin, Atlanta was installed as president. Dr Edgar D Shanks, Atlanta, was elected secretary to succeed Dr Allen H Bunce. Dr Bunce has been a member of the Board of Trustees of the American Medical Association since 1929. The next annual session of the association will be held at Savannah May 12-15, 1936.

ILLINOIS

Society News—Dr G Henry Mundt, Chicago addressed the Livingston County Medical Society, Pontiac, April 18 on 'The Relation of Medicine to the Body Politic'.—Drs Aaron Arkin and Harry Culver, Chicago, addressed the Decatur Medical Society, April 23, on 'Blood Dyscrasias and Traumatic Lesions of the Urinary Tract,' respectively. Dr Arkin conducted a clinic on heart disease during the day.—Dr William H G Logan, Chicago, addressed a joint meeting of the Warren County medical and dental societies, April 25 on 'Common Lesions and Abnormalities of the Face, Mouth and Jaws'.—Dr Maurice L Blatt, Chicago, was the speaker at a meeting of the Whiteside County Medical Society April 25, on 'Convulsions in Children: Diagnosis and Treatment'.—Dr Samuel Soskin Chicago discussed diabetes mellitus at a meeting of the Will-Grundy Counties Medical Society, April 24.—Dr Sumner L S Koch, Chicago, spoke before the Fulton County Medical Society, April 24 on 'Repairs of Defects of the Superficial Tissues Resulting from Burns and Injuries.'

Chicago

Personal—At a banquet in his honor, April 24 Dr Max Thorek was made a chevalier of the French Legion of Honor in recognition of his contributions to surgical science and humanitarian work among the poor. Consul General Rene Weiller conferred the decoration.

Society News—Puerperal infections occurring in maternal deaths in 1933 was the theme of the meeting of the maternal welfare committee of the Chicago Gynecological Society May 21. Dr Abraham F Lash, assistant professor of obstetrics and gynecology University of Illinois College of Medicine, presented the topic and Dr Julius E Fleischner discussed it. The committee has been conducting a survey of maternal deaths in the city for three years and plans to continue for at least one more year.

Lecture on "Heroes in Medicine"—Withrow Morse Ph D New York, will give an illustrated lecture on "Modern Heroes in Medicine" at the Allerton Hotel, 701 North Michigan Avenue, June 9. The courage shown by workers in developing scientific facts will be illustrated by a sound motion picture and by slides. Dr Anton J Carlson, professor of physiology, University of Chicago, will introduce the speaker. Dr Morse served as professor of biochemistry successively in the medical departments of the Universities of Nebraska and West Virginia and Jefferson Medical College, from 1916 to 1929. There will be no admission fee, and a cordial invitation is extended to physicians. The lecture will be at 8:30 p m.

Dr Tahaferro Named Dean of Biologic Division—William H Tahaferro, Ph D., associate dean, Division of Biological Sciences, University of Chicago, and chairman of the department of hygiene and bacteriology, has been appointed dean of the division to succeed Frank R Lillie, Ph D., Andrew MacLeish distinguished service professor of embryology, whose retirement at the age of 65 is effective this year. Dr Tahaferro who will take over his new duties July 1, is also professor of parasitology. He is 40 years of age and graduated from the University of Virginia in 1915. He received his degree of doctor of philosophy from Johns Hopkins University in 1918. He taught protozoology at Johns Hopkins from 1919 to 1924, when he became affiliated at the University of Chicago as associate professor of parasitology. In 1927 he was made professor in this subject and in 1931 became associate dean of the division. Dr Lillie earned his philosophy degree at the University of Chicago in 1894. The following six years he served on the staffs of the University of Michigan and Vassar College. In 1900 he began his association with the University of Chicago and in 1907 was made professor of embryology. In 1911 he was made chairman of the department of zoology and in 1931 dean of the Division of Biological Sciences. Since 1925 he has been president of the Marine Biological Laboratory at Woods Hole Mass. He was managing editor of the *Biological Bulletin* from 1902 to 1926 and was formerly associate editor of the *Journal of Experimental Zoology*. Dr Lillie was recently elected president of the National Academy of Sciences and chairman of the National Research Council, Washington D C. Dr Arthur C Bachmeyer, director of the University Clinics, has been made associate dean of the division.

INDIANA

Society News—Dr Joseph Brennemann, Chicago, discussed acute conditions of the abdomen in the child before the Tippecanoe County Medical Society in Lafayette, April 11.—Dr Aaron Arkin Chicago, discussed 'Differential Diagnosis of Organic Heart Disease' before the LaPorte County Medical Society in Michigan City, April 18.—The Muncie Academy of Medicine was addressed in Muncie, April 30, by Dr Merritt Paul Starr Chicago, his paper was entitled 'The Clinical and Physiological Relation of the Pituitary to the Thyroid'.—At a joint meeting of the Miami County Medical and dental societies in Peru, March 29, focal infections were discussed by Dr Benjamin F Eikenberry and John P Van Osdel DDS.—A symposium on the surgical pathology of appendicitis was presented before the Huntington County Medical Society in Huntington April 2, by Drs William C Moore and Lall G Montgomery Muncie.—At a meeting of the Fort Wayne Medical Society in Fort Wayne, April 16, Dr Cyrus C Sturgis Ann Arbor Mich, discussed treatment of the anemias.—Dr George H Gardner, Chicago, addressed the Northeastern Indiana Academy of Medicine in Kendallville April 25, on 'The More Common Pelvic Infections: Etiology, Pathology, Differential Diagnosis Treatment and Prevention'.—The Madison County Medical Society was addressed in Anderson April 15, by Dr Francis C Guthrie on 'Cardiac Pathology and Its Interpretation.'

KANSAS

Personal—Dr Charles M Siever for nineteen years head of the student health department at Kansas State College Manhattan resigned, April 1. Dr Siever, whose resignation will become effective August 31, practiced in Holton from 1909 to 1916, serving as health officer of Jackson County six years of this time. He will probably continue private practice in Manhattan it was stated.—Dr Alonzo R Adams president of the Leavenworth County Medical Society, has been appointed city physician and health officer of Leavenworth.—Dr Joseph W Spearing, Cimarron, has been appointed health officer for Ford County.

Society News—Dr Andrew B Rivers, Rochester, Minn, addressed the Sedgwick County Medical Society, Wichita, April 19 on the diagnosis and treatment of peptic ulcer.—The Reno County Medical Society was addressed in Reno

March 1, among others, by Drs Ralph H. Major, Kansas City, Mo., on "Hippocrates and the Isle of Cos," and Cecil G. Leitch, Kansas City, Mo., "Pathology of Sudden Death from Heart Disease."—Dr Thomas G. Orr, Kansas City, Mo., addressed the Shawnee County Medical Society in Topeka, April 1, on "Fractures of the skull."—Dr William J. Feehan, Kansas City, Mo., addressed the Wyandotte County Medical Society, March 20, on "Emergency Treatment of Simple and Compound Fractures." The society was addressed March 27, by Dr Harold V. Holter, Kansas City, on "Obstetrical Shock and Embolism."

LOUISIANA

Society News—Speakers before the Orleans Parish Medical Society, New Orleans, April 8, were Drs Michael E. DeBakey and Edward William Alton Ochsner on "Diagnosis and Treatment of Amebic Hepatic Abscess," and John Sig-norelli, "Chronic Abdominal Discomfort in Children." Speakers before the society, May 13, included Drs James K. Howles and Edward William Alton Ochsner on "Mycotic Infections of the Skin" and "Total Ablation of the Thyroid in Cardiac Disease," respectively. The society was addressed, April 22, on acute mercury poisoning by Drs Edgar Hull and Louis A. Monte F. Boyce.—Dr Charles L. Scudder, Boston, addressed the Fourth District Medical Society in New Orleans, March 5, on "Fractures of the Hip and Spine" and Dr James B. Vaughan, Monroe, "The Cardiograph in the Diagnosis of Heart Disease."—Dr Charles J. Bloom has been elected president of the Louisiana State Pediatric Society, and Dr Ruth G. Aleman, New Orleans, vice president.

MARYLAND

Personal—C Leroy Ewing, director bureau of laboratories, Baltimore City Health Department, was elected president of the Maryland Society of Bacteriologists recently.—The honorary degree of doctor of laws will be conferred on Dr James M. H. Rowland, dean, University of Maryland School of Medicine, Baltimore, by Washington College, Chestertown, at the annual commencement.—Dr Mabel I. Silver has returned to Baltimore on furlough from her station at Tama, West Africa.

Negro Death Rates Decline—The general death rate per thousand of the total Negro population was 168 in 1934 as compared with 233 in 1915. Similar declines were noted in morbidity rates 204.3 in 1934 as compared with 402.1 in 1915 for tuberculosis, typhoid 7.6 in 1934 as against 47.2 in 1915 and 0.7 in 1934 against 7.1 in 1915 for diphtheria. The colored infant mortality rate per thousand live colored births was 104.1 in 1934 while 1915 showed a rate of 195.5. Increases were noted for heart disease and cancer, the respective rates being 258.6 and 87 in 1934 as compared with 222.4 and 55.2 in 1915.

Health Department Staff Meetings—Dr Joseph Earle Moore, associate in medicine, Johns Hopkins University School of Medicine, addressed the third meeting of the medical staff of the Baltimore City Health Department, April 12, on syphilis. These meetings were instituted February 8, when Dr Lewellys F. Barker spoke. Dr Victor F. Cullen, State Sanatorium, addressed the March meeting on tuberculosis. The medical staff is made up of seventy-four physicians, eleven of whom serve on a full time basis. The remaining sixty-three are engaged in private practice and act as health officers in the prenatal infant and school hygiene services, in connection with the control of tuberculosis or the venereal or other communicable diseases.

MICHIGAN

Exhibition of Hobbies—The Woman's Auxiliary of the Wayne County Medical Society Detroit sponsored the second annual exhibition of hobbies by members of the profession, their wives and families April 12-19. The display included china photographs, anatomic drawings, pottery, watercolors and metal work.

Society News—Herbert V. Barbour, chief counsel of the Michigan State Medical Society, addressed the Oakland County Medical Society in Pontiac April 17 on "Legal Problems and the Practice of Medicine."—Dr William Wayne Babcock, Philadelphia, addressed a meeting in Grace Hospital, Detroit, April 12 on "Diagnosis and Management of Carcinoma of the Intestinal Tract."—Among others Dr Robert F. Ridpath, Philadelphia, addressed the twenty-fifth anniversary meeting of the Detroit Otolaryngological Society April 24 on "Voice Production and the Various Characteristics of the Voice."—Dr Fred L. Adair, Chicago, spoke before a joint meeting of the Detroit Pediatric Society and the Detroit Obstetrical and Gynecological Society April 3 on "Birth Trauma in Relation

to Fetal Deaths and Neonatal Morbidity and Mortality."—Dr Alexander A. Goldsmith, Chicago, addressed the Kalamazoo Academy of Medicine, April 16, on "Regional Ileitis."—Dr Louis A. Brunsting, Rochester, Minn., addressed the Kent County Medical Society, April 24, on "Changing Conceptions of Eczema."—Dr Burrill B. Crohn, New York, discussed "Nonspecific Ulcerative Colitis" before the medical section of the Wayne County Medical Society, April 1. Dr Irving S. Cutter, dean, Northwestern University Medical School, Chicago, addressed a joint meeting of the society and the woman's auxiliary on "Contemporary Medicine," April 8. The Noon Day Study Club and the dramatic section of the society presented three one act plays, April 1. A Leap Year Bride, "The Dance Below" and "Before Breakfast."

MINNESOTA

Memorial to Lucretia Wilder—Funds are being solicited by a committee at the University of Minnesota Medical School to establish either a memorial tablet or a scholarship prize in honor of the late Miss Lucretia Wilder, who died as the result of an infection received in the pursuit of her research work on leukocytosis. Contributions should be sent to Dr Elias P. Lyon, dean, 136 Medical Service Building, University of Minnesota, Minneapolis.

Society News—The Hennepin County Medical Society was addressed May 6 by Dr Edward H. Rynearson, Rochester, on "Recent Advances in the Study of the Endocrine Glands, with Special Reference to the Relationship of the Pituitary Gland to the Carbohydrate Metabolism as Well as Its Role in the Sex Cycle of the Female."—Dr Henry W. Meyerding, Rochester, addressed the Becker-Clay Counties Medical Societies at Sand Beach, March 29, on bone surgery.

NEW JERSEY

Personal—Philip McKim Garrison, secretary of the pharmaceutical firm of Merck & Co., Rahway, aged 65, died in New York, March 20, of anemia.—Members of the Machaon Club of Hudson County and other friends met at a dinner in honor of Dr Levings A. Opdyke, Jersey City, April 3, celebrating his fiftieth anniversary in the practice of medicine.—Drs Alexander Macalister, Camden, and John W. Marcy, Merchantville, were guests of honor at the meeting of the Camden County Medical Society, Camden May 7, marking the fiftieth anniversary of their graduation from the University of Pennsylvania School of Medicine. Both received embossed scrolls attesting their service.

Society News—Drs John R. Finley, New York, and Arthur W. Bingham, East Orange, addressed the Bergen County Medical Society April 9, on "Postpartum Care" and "Prenatal Care," respectively.—Drs Charles F. Geschickter and Murray M. Copeland, Baltimore, addressed the Essex County Medical Society Newark, on "Benign Tumors of the Breast and Their Endocrine Relationship" and "Cancer of the Breast in Relation to Diagnosis and Treatment," respectively.—The Essex County Anatomical and Pathological Society celebrated its twenty-fifth anniversary February 28, with a dinner, at which Dr Harrison S. Martland, Newark, was the guest of honor.—Dr Israel Strauss, New York, addressed the Hudson County Medical Society May 7 in Jersey City on "Encephalography and Its Diagnostic Significance."

NEW YORK

A Member Fifty Years—The Ontario County Medical Society at its spring meeting, April 9, paid honor to Dr George W. Sargent, Seneca Castle, who has been a member of the society for fifty years. Following a dinner at Clifton Springs Sanitarium, Clifton Springs, Dr Arthur J. Bedell, Albany, president of the Medical Society of the State of New York, made the congratulatory address. Dr Sargent graduated from the Syracuse University College of Medicine in 1879.

Personal—Dr Henry R. O'Brien, Albany, has been appointed health officer of Cattaraugus County to succeed Dr Reginald M. Atwater, who resigned to become executive secretary of the American Public Health Association.—Dr Spencer L. Dawes, medical examiner of the state department of mental hygiene since 1919, retired April 1.—Walter L. Hutchins, assistant secretary of the New York State Department of Mental Hygiene for the last twelve years, died at his home in Albany, April 21 after a brief illness.

Septic Sore Throat Due to Contaminated Milk—An epidemic of about 250 cases of septic sore throat at Baldwinsville, Onondaga County, was reported by the state department of health April 15. More than 90 per cent of those attacked were customers of a single dairy, which supplies about 450

quarts a day from five different farms. Investigation revealed that a cow on one farm was suffering from mastitis of a type previously encountered in outbreaks of septic sore throat. The disease was said to be severe, but no deaths had occurred up to the time of the report.

Society News—Dr Nels A Nelson, Boston, addressed a special meeting of the Syracuse Academy of Medicine April 30, on "Epidemiology of Syphilis."—Dr Frederic E Elliott, Brooklyn, addressed the Medical Society of the County of Erie, April 30, on health insurance.—At the annual meeting of the New York State Dental Society in Upper Saranac, June 12-15, Drs I Newton Kugelmass and Douglas Quick, New York will speak on "Medical Management of Dental Caries in Children" and "Cancer of the Mouth Its Prevention and Early Diagnosis," respectively, and Dr Arthur Q Penta, Saranac Lake, N Y, on "The Role of the Oral Spirochete and Associated Anaerobes in Pyorrhea and Pulmonary Suppuration."

New York City

Faculty Changes at New York University—Dr Lewis D Stevenson has been appointed assistant professor of neuropathology and Dr Howard C Taylor, assistant professor of obstetrics and gynecology. In addition the following promotions have been announced:

Dr Edward R Maloney to associate professor of dermatology and syphilology

Dr Evan W McLave to assistant professor of clinical medicine

Dr Horold R Merwarth, to clinical professor of neurology

Dr Meredith F Campbell to clinical professor of urology

Dr Aaron Brown to assistant clinical professor of medicine

Dr Morris Goodman to assistant clinical professor of medicine

Dr William H Lewis Jr assistant clinical professor of medicine

Hospital News—New laboratories were opened at the Hospital for Ruptured and Crippled, April 17, with a ceremony at which Dr Robert B Osgood, emeritus professor of orthopedic surgery, Harvard University Medical School, Boston, delivered the principal address. The new department occupies a wing of the sixth floor and includes a medical museum and a library, in addition to facilities for research.—Ground was broken, April 7, for a new wing at the Richmond Memorial Hospital, Prince's Bay, Staten Island, which will double the capacity of the hospital, now forty-five beds. The addition is the gift of Mrs Louis A Dreyfus, who has previously given large amounts to the hospital.

Society News—The Medical Society of the County of Queens met with the Queens County Bar Association, April 30, for the following program: Mr Lorenz Brosnan, "Medico-legal Relationship Between Physician and Patient"; Mr Charles P Sullivan, "The Criminal Legal Relationships of Medical Practice," and Dr Charles Norris, "Modern Forensic Medical Practice."—Dr François Ackermann, Geneva Switzerland, lately of the Faculty of Medicine and Dentistry of the University of Geneva, Switzerland was guest of honor at the annual banquet of the American Stomatological Association April 3. He delivered an address on "The Local Proximal and General Modifications Resulting from Normal Occlusion."

Presumptive Diphtheria Carriers—The procedure for administrative control of diphtheria carriers has recently been modified by the department of health. The term "presumptive diphtheria carriers" has been introduced to define a person who harbors diphtheria-like bacilli but who gives no history of a recent sore throat or nasal discharge, or who harbors diphtheria-like bacilli but has not been in contact with a recent case of diphtheria. These presumptive carriers will be visited, but they will not be isolated or their premises quarantined. Arrangements have been made for prompt testing of such persons for virulence of the bacilli and according to the results the carrier will be classified as "diphtheria carrier" or "no case," according to the department's bulletin. They will be excluded from school and prohibited from going out of town until the result of this test is reported. It is believed that the new procedure will relieve hardships sometimes imposed on harmless carriers of nonvirulent bacilli.

NORTH CAROLINA

University News—Dr Foster Kennedy, New York, gave the second annual lecture sponsored by Nu Sigma Nu at Duke University School of Medicine, April 13 on "The Relation of Neurology and Psychiatry to General Medicine."—A new 400,000 constant potential volt x-ray machine has been installed at Duke Hospital.

State Medical Election—Dr Charles F Strosnider, Goldsboro, was named president-elect of the Medical Society of the State of North Carolina at its annual meeting in Pinehurst May 6-8, and Dr Paul H Ringer, Asheville, was inducted into the presidency. The next annual session will be held at Pinehurst, May 4-6 1936.

OHIO

University News—Drs Adolphus W Foertmeyer, Douglas A Johnston and Clyde E Shinkle were advanced from instructors to assistant professors in psychiatry at the University of Cincinnati College of Medicine at the March meeting of the board of directors.

Personal—Dr Rezin J Pumphrey, Massillon, was honored by a dinner, April 9, celebrating the fiftieth anniversary of his entrance into medical practice. Dr George W Crile, Cleveland, was the principal speaker.—Dr John D Schonwald, Oxford, has been named medical director of Miami University, succeeding Dr Wade MacMillan, who recently retired.—Dr William A McMichael, Keene, has been appointed health officer of Coshocton County to succeed Dr Samuel B Kistler, Coshocton.

Annual Cincinnati Homecoming—The University of Cincinnati College of Medicine will hold its annual reunion and homecoming June 8. Dr Marion A Blankenhorn, who becomes head of the department of internal medicine at the school, September 1, will be the guest of honor and principal speaker. Dr Ben L Bryant, president of the Alumni Association, will preside at the banquet. The following program will be presented Saturday morning:

Dr Robert A Kehoe Lead Poisoning with Special Reference to Laboratory Diagnosis

Dr George M Guest The Anemias of Early Childhood

Dr William M Millar Newer Aspects of Radium Therapy in the Management of Malignant Disease

Dr Johnson McGuire Electrocardiography

The afternoon will be devoted to a series of round table discussions. Recent Advances in Hematology, Dr Leon Schiff. Diagnosis and Treatment of Diseases of the Biliary Tract and Pancreas, Dr Max M Ziminger, and Peripheral Vascular Disease, Dean Alfred Friedlander and Louis Herrmann. All graduates of the College of Ohio, Miami and the University of Cincinnati College of Medicine are cordially invited.

PENNSYLVANIA

Montour County Graduate Assembly—The monthly graduate assembly presented by the Montour County Medical Society for April was held at Geisinger Memorial Hospital, Danville. Dr William Wayne Babcock, Philadelphia, conducted a dry clinic on differential diagnosis of general surgical conditions, other guests were Drs Norris W Vaux and Clifford B Lull, Philadelphia, who presented a symposium on obstetrics.

Personal—Dr Charles S Aitken Brookline, was appointed coroner of Delaware County recently to succeed Dr James Evans Schiehle Llanerch, who resigned to become state secretary of welfare.—Dr John M Dumin, Mackeyville, has presented an acre of land to the Lock Haven Kiwanis Club as a permanent site for the Kiwanis Health Camp. For the past two years the club has maintained a camp in cooperation with the Clinton County Tuberculosis Society for fifty underprivileged children.—Dr Martin E Griffith, Monessen, was guest of honor at a dinner given by the Kiwanis Club of Monessen, April 2, celebrating his fiftieth anniversary in the practice of medicine.—Dr James T Strimple Erie, was recently appointed health officer of Erie County, succeeding Dr Richard O Miller.

Philadelphia

Personal—Dr John A Kolmer received the Poor Richard Medal of achievement, awarded by the Poor Richard Club April 4, in recognition of his work on poliomyelitis vaccine.—Dr Alfred N Richards, professor of pharmacology, University of Pennsylvania, will receive the honorary degree of doctor of laws from the University of Edinburgh in June, Science reports.

Needy Medical Students Aided—The University of Pennsylvania has been made the beneficiary of most of the \$115,000 estate of the late Dr Delno E Ketcher according to the New York Times. A loan fund will be created for needy students in the medical school who have satisfactorily completed the first year medical course. Graduate students and research workers in medical science will also be entitled to aid.

Newbold Lecture—Dr C U Ariens Kappers director of the Institute for Brain Research at Amsterdam and professor of comparative anatomy, University of Amsterdam, delivered the thirty-fourth Mary Scott Newbold Lecture of the College of Physicians of Philadelphia, May 1. His subject was "Development of the Different Layers of the Cerebral Cortex with Reference to Some Pathological Cases, the Forebrain of Prehistoric Races."

Hospital News—Dr Karl Lindner, Vienna, Austria, gave a series of four lectures at Wills Eye Hospital, April 15-18, on cause and treatment of retinal detachment, clinical pathology of the vitreous, present operations for the treatment of ptosis, and glaucoma and extraction of cataract—A clinic for the administration of protective serum against poliomyelitis was opened at Temple University Hospital recently by Dr John A Kolmer

Society News—Dr Edward C Rosenow, Rochester, Minn, addressed the Academy of Stomatology of Philadelphia April 23, on 'The Present Status of Focal Infection Problems'—Drs Leon H Cornwall and Richard M Brickner, New York, addressed the Philadelphia Neurological Society, April 26 on 'Experimental Production of Multiple Sclerosis' and 'Treatment of Multiple Sclerosis,' respectively—Dr J Nor- man Henry, health director of Philadelphia and Louis I Dublin, Ph D, New York, addressed the Philadelphia Metabolic Asso- ciation, March 29 on 'Public Health Aspects of Diabetes' and 'Diabetes Mellitus, Its Incidence and Epidemiology and Its Relationship to Heredity and Obesity' respectively—Dr Ben- jamin P Potter Secaucus N J addressed the Philadelphia Roentgen Ray Society May 2 on 'Bronchography as an Aid in the Interpretation of X-Ray Shadows Cast by Pleuropul- monary Changes in Tuberculosis'

SOUTH DAKOTA

Society News—Dr Byrl R. Kirklm, Rochester Minn, addressed the Aberdeen District Medical Society recently, on 'Diagnosis of Carcinoma of the Stomach'—At the spring meeting of the Yankton District Medical Society in Vermilion, April 24, Dr Nelms J Nessa Sioux Falls, discussed 'Thera- peutic Applications of X-Rays in Medicine'—Gilbert G Bicknell DDS, Yankton "Dental X-Rays as a Diagnostic Aid" and William E Donahoe, Sioux Falls "Economics of Organized Medicine"—The Seventh District Medical Society met at Sioux Falls April 9 with Dr Frank B Kirby North Chicago Ill, as speaker on 'Professional Economics'—Speakers at a meeting of the Huron District Medical Society in March at Huron were Aberdeen physicians Drs John L Calene on hypothyroidism Roland G Mayer hematuria, and Earle A Pittenger medical economics

TEXAS

Society News—Dr Frank D Dickson, Kansas City was guest speaker at the semiannual meeting of the Texas Surgical Society in San Antonio April 8-9 presenting 'A Survey of the Management of Intracapsular Fracture of the Neck of the Femur'—Drs Roy G Giles and George V Brindley Temple among others addressed the Bell County Medical Society April 3 on 'Filtration for Maximum Effects at Different Depths in Roentgen Therapy and 'Carcinoma of the Colon,' respectively—Dr Robert H Millwee Dallas among others addressed the Anderson-Houston Counties Medical Society Palestine April 2 on 'Development and Behavior of Cancer Cells'—Speakers at a meeting of the Falls County Medical Society Marlin April 8 were Drs John Walter Torbett Jr and Neil D Buie, Marlin, on 'Use of Short Wave Therapy in Medical Con- ditions' and 'Hypertension Treated by Spa Method' respec- tively

VIRGINIA

Faculty Changes—The Medical College of Virginia, Rich- mond, announces the following changes and additions to the faculty, among others, for the session 1935-1936
Drs Frederick M. Hodges and Daniel D Talley Jr professors of clinical radiology
Dr Harry Walker assistant professor of medicine.
Dr Irl C Riggan state health officer lecturer in preventive medicine and public health

Society News—Drs William T Green Jr Nassawadox, and Joseph H Hiden Pungoteague addressed the Eastern Shore of Virginia Physicians Journal Club at Nassawadox, February 12, on refraction of the eye and on scarlet fever respectively—The Virginia Peninsula Academy of Medicine was recently organized at a meeting in Newport, with Drs Edward L Alexander Newport News as president and Frank S Bacon, Hampton, as secretary—At the quarterly meeting of the Southside Virginia Medical Association in Petersburg, March 12, speakers included Drs W Ambrose McGee, Rich- mond on 'Early Diagnosis Prevention and Treatment of Whooping Cough' Richard F Slaughter Jr Norfolk 'Treat- ment of Acute Head Injuries,' and John Shelton Horsley, Richmond 'Glomus Tumor'—Dr Stuart N Michaux, Rich- mond, addressed the Lynchburg Academy of Medicine, March 4, on 'Etiology and Treatment of Cystocele and Uterine Pro- lapse, with Special Reference to the Watkins-Wertheim Method of Treatment'—Drs Thomas M Rivers New York and

Emil Novak, Baltimore, addressed the Roanoke Academy of Medicine, February 4, on 'Virus Encephalitis' and "Gyneco- logic Aspects of Endocrinology," respectively—Among other speakers, Drs Mason Romaine, Wilbur M Bowman, Leta J White and William B McIlwaine III, al' of Petersburg, pre- sented a symposium on anterior poliomyelitis at a meeting of the Postgraduate Medical Society of Southern Virginia at Hopewell recently

WEST VIRGINIA

Society News—The Cabell County Medical Society at its March meeting adopted a resolution condemning health insur- ance conducted by government, national, state or local, and authorized the committee on public policy and legislation to communicate this decision to West Virginia representatives in Congress—Drs Karl G Zwick and Samuel L Bauer, Cincin- nati, spoke on 'Past and Present Concepts of Eczema and Its Treatment' and "Eczema in Children," respectively—Dr John A Kolmer Philadelphia, addressed the Parkersburg Academy of Medicine recently, on 'The Role of Vaccines in the Treat- ment of Diseases'—Dr Martin L Bonar, Charleston, addressed the Harrison County Medical Society, Clarksburg, March 7, on "Treatment of Syphilis"

GENERAL

Northwest Medical Meeting—The fourteenth annual meeting of the Pacific Northwest Medical Association will be held at the Davenport Hotel, Spokane, Wash June 27-29 The following physicians will be on the program
Loyal Davis Chicago Brain Surgery
J Edwin Wood Jr University Va Medicine
Arno B Luckhardt Chicago Physiology
Tracy B Mallory Boston Pathology
George E Brown Rochester Minn Vascular Diseases
Fred W Rankin Lexington Ky Surgery

In addition there will be a lecture on obstetrics, the speaker to be announced later

Dr Cushing Awarded Another Medal—At its annual dinner in New York, May 9, the National Institute of Social Science conferred its gold medal on Dr Harvey Cushing, New Haven Conn., in recognition of "distinguished services rendered to humanity" Following his graduation at Harvard in 1895 Dr Cushing engaged in the practice of surgery He was associated with Johns Hopkins University School of Medicine from 1902 to 1912 then he was Moseley professor of surgery at Harvard and surgeon-in-chief at Peter Bent Brigham Hospital until his retirement in 1932 The following year he became the first incumbent of a new chair at Yale University School of Medicine the Sterling professorship of neurology Many hono- ary degrees have been conferred on Dr Cushing In 1922 he was awarded the Charles C Mickle Fellowship of \$1,000 by the University of Toronto Faculty of Medicine This prize is given to the member of the profession considered by the faculty to have done most during the preceding ten years to advance sound knowledge of a practical kind in medical art or science During the World War he was a colonel in the medical corps and director of U S Base Hospital number 5 (Harvard base hospital unit) He received the Lister Medal of the Royal Col- lege of Surgeons in 1930 He was president of the American College of Surgeons and the American Neurological Association in 1923, and of the American Surgical Association in 1927 He was the recipient of the Cameron Prize of the University of Edinburgh in 1924 Dr Cushing's The Life of Sir William Osler won the Pulitzer Prize for biography in 1925

Bequests and Donations—The following bequests and donations have recently been announced

Northern Westchester Hospital Mount Kisco N Y \$10,000 by the will of the late Mrs Margaret Jardine Addicks Greenwich Conn
The following New York City hospitals were beneficiaries in the will of the late Mrs Mary Strong Skattuck St Luke's Hospital \$35,000 Bellevue Broad Street and Women's Hospitals \$25,000 Babies Hospital \$15,000 and New York Eye and Ear Infirmary \$10,000
J Miller
Lankenau Hospital Philadelphia \$10,000 by the will of the late Emile Wood, Omaha
Methodist Hospital Omaha \$10,000 as a gift from Dr and Mrs I C Philadelphia General Hospital \$20,000 Kensington Hospital for Women \$10,000 Visiting Nurse Society St Christopher's Hospital for Children and Maternity Hospital of Philadelphia each \$5,000 under the will of the late George Leib Harrison
The Emma L Bixby Hospital Philadelphia
of Mrs Helen A Bray Adrian Mich. \$25,000 by the will of the late Mrs Helmbold
Delaware County Hospital Drexel Hill Pa \$5,000 under the will of the late Mrs Helmbold
Manhattan Eye Ear and Throat Hospital New York, \$35,000 and Lydia Evelyn Danczuk
Chestnut Hill Hospital Philadelphia \$10,000 by the will of Mrs Elizabeth Cuthbert Roberts Wyatt
An estate estimated at more than \$700,000 is to go to the Salem Hospi- tal Salem Mass when it reaches \$1,000,000 according to the will of the late John H Frazier Marblehead

Memorial Hospital and Habnemann Hospital Worcester Mass \$10 000 each through a trust fund established by the late Eli Collier and the will of his daughter Etta C Collier Johnson

Among bequests by the late Adolph S Ochs publisher of the New York Times was a fund of \$5 000 for a portrait bust of Dr J Bentley Squier to be placed in the Squier Urological Clinic of Presbyterian Hospital New York

Yonkers General Hospital and St Joseph's Hospital Yonkers \$25 000 each, and St John's Riverside Hospital Yonkers \$150 000 from the Surdna Foundation

The Children's and Episcopal Hospitals Philadelphia \$10 000 each from the trust estates of Elizabeth C and Frances A Roberts

Children's Hospital Philadelphia, \$12 000 under the will of the late Mrs Laura A Hollar to endow a free room to be called the William A Hollar Memorial Room

Episcopal and Methodist Episcopal hospitals Philadelphia \$5 000 each by the will of the late William S Vane

Medical College of Virginia Richmond \$1 500 for a fellowship in the department of pharmacology for research on digitalis by Rare Chemicals Inc Napa Park N J \$1 200 for research on arthritis by Eli Lilly & Co Indianapolis and Parke Davis & Co \$1 500 for research in the department of pathology

New York University College of Medicine about \$180 000 and the New York Academy of Medicine \$1 000 by the will of the late Dr William Chittenden Lusk

French Hospital New York and Monmouth Memorial Hospital Long Branch N J \$116 070 each by the will of the late John Hubbard

Jefferson Medical College Philadelphia a fund of \$63 000 left by Mrs Jennie M Shoemaker for aid of needy students as a memorial to her husband Dr John V Shoemaker who was head of the old Medico Chirurgical College at the time of his death in 1910 The fund has been held in trust since Mrs Shoemaker's death in 1921

University of Pennsylvania \$125 000 to found the George de Benneville Keim Memorial income from which is to be used for the medical school \$50 000 in trust for the graduate school of the university for research in internal medicine through the will of Mrs Sarah Keim Montgomery

FOREIGN

Cameron Prize—The University of Edinburgh has awarded the Cameron Prize for 1935 to Dr Julius Wagner-Jauregg, emeritus professor of psychiatry and neuropathology in the University of Vienna, in recognition of his discoveries in connection with malarial treatment of dementia paralytica, *Science* announces

Congresses in Brussels—The fourteenth annual session of the 'Medical Days' in Brussels will be held June 29-July 3, with physiopathology of the endocrine glands as the principal topic of discussion. It is expected that this session will be more than usually interesting because of the international exposition in progress in Brussels. For information address Dr Rene Beckers, secretary general, 141 rue Belliard Brussels, Belgium. The eighth International Congress of Military Medicine and Pharmacy will be held at the same time, beginning June 27. Information concerning this meeting may be obtained from the general secretary, Health Service Ministry of National Defense Brussels.

Society News—The International Congress on Life Assurance Medicine will be held in London, July 23-27. Among other speakers will be Drs Chester T Brown, medical director of the Prudential Life Insurance Company, Newark, N J, on "Methods of Estimating Risks," and Samuel B Scholz Jr, medical director of the Penn Mutual Insurance Company, Philadelphia, on "The Role of Health Service in Life Insurance."—The twelfth International Congress of Pharmacy will be held in Brussels Belgium July 30-August 5. J Breugelmanns 3 rue du Gouvernement Provisoire, Brussels, is secretary.—Prof Fernand Bezançon, Paris, has been chosen general secretary of the International Union Against Tuberculosis succeeding the late Dr Léon Bernard.

Hungarian Memorial Volume—A special issue of the *Orvosképzés* (Hungarian Medical Postgraduate Journal, published by the Hungarian Medical Postgraduate Central Committee, Budapest) has just been issued in commemoration of the 300th anniversary of the Royal Hungarian University of Sciences. The volume is dedicated by the Hungarian Medical Postgraduate Central Committee to its alma mater. The president of the committee is Prof Dr Emil de Grósz. The other officers and members of the committee are the professors of the various faculties of the university. A complete list of the names is shown on the front of the cover page of the volume. The contents of the volume comprise articles written by Prof Freiherr Anton von Eiselsberg, Vienna, Prof Ludwig von Aschoff Freiburg im Breisgau, Prof R. Anthony Paris, the members of the committee, and other Hungarian professors and prominent scholars in the various faculties of medical science. The subject matter of the articles is medical education in the various branches of medical science as applied in the universities of Hungary at present with reference to its historical development. One article is on the education in public hygiene in the civilized countries, as at present. Several articles are written in French, several in German one in Italian and the most in Hungarian. The *Orvosképzés* is published bimonthly and the memorial volume is a special issue published in the twenty-fifth year of the journal's existence.

May 4 1935

No Increase of Malnutrition

Attempts have been made by the labor party to represent maternal mortality and other matters of public health as due to malnutrition and the result of insufficient unemployment dole. These allegations have always been shown to be unfounded. In December last a letter appeared in the *Times* from a Sunderland physician maintaining that between the Tyne and the Tees (a large industrial area in the north of England where unemployment is rife) there was, in spite of what the chief medical officer of the ministry of health said in his last two reports a substantial and progressive deterioration in public health. The minister of health immediately appointed some of his higher officials to make an investigation. They visited the area and reported that the death rates from bronchitis and pneumonia, and the case mortality rate from scarlet fever and diphtheria do not indicate an unfavorable effect of the present economic conditions. Tuberculosis and rickets told the same story. A general survey of the population showed in 75 per cent a good standard of health. The remainder manifested a varying degree of subnormality grading from minor manifestations to what for want of a better name may be termed 'malnutrition.' But these terms are to be construed in relation not only to diet but also to environment, family care, habits and recent or active illness. From their own knowledge of the district since 1928 these officials could see no evidence of deterioration. With an occasional exception the consensus of medical opinion in the district confirmed this conclusion. The conditions in the town of Sunderland were less favorable but this is attributed to less favorable housing and to environment. Realizing the long continued economic stress and with knowledge of the home conditions the officials were often surprised at the high standard of health and courage maintained.

The Health of the Navy

The report on the health of the navy for 1933 just issued shows an increase of the incidence of disease compared with 1932 and the five year average from 1928 to 1932. The total force was 83 125 and the total number of cases of disease and injury 41 852. Medical officers had difficulty in deciding how to return the catarrhal epidemics that occur in ships each winter. Many returned them as "epidemic catarrh", but, as it is impossible to draw a line between this and an epidemic of mild influenza all these cases are now shown under this heading. They numbered 3 770. It has been shown that excrement from seagulls in areas in which the sea water is contaminated with sewage may contain *Bacillus typhosus*. Automatic chlorinators are being fitted to the dockyard wells in Sheerness, as these have sometimes been found to contain impurities. A salt water swimming bath in an establishment at Gosport for training boys was shown bacteriologically to be grossly contaminated.

The Epidemic of Malaria in Ceylon

The serious epidemic of malaria in Ceylon, after some diminution is again assuming greater proportions. Colonel Gill the expert adviser from India is touring the affected districts. The experiment of treatment with the new drug atebri-musonate appears to be successful. The sponsor for this drug is Dr A T W Simeons who arrived in January. He has had much experience in India Africa and Siam and at the Institute of Tropical Diseases at Hamburg. So confident is he of the value of the drug that he has offered his services free to the government of Ceylon. The total number of deaths

registered in Ceylon during the five months from November to March was 113,811, compared with 47,107 in the corresponding period of last year. The excess is attributed to malaria.

The Robert Jones Memorial

The Council of the Royal College of Surgeons has agreed to the suggestions of the Robert Jones Memorial Fund Committee for the foundation of a Robert Jones professorship of the Royal College of Surgeons of England for an annual lecture or lectures on some subject connected with orthopedic surgery (sum allocated \$5,000) and for the foundation of a traveling research fellowship to be awarded alternately by the University of Liverpool and the Liverpool Medical Institute jointly, and the Royal College of Surgeons (sum allocated \$10,000).

The Future of Radiologic Diagnosis

At a meeting of the Medical Society of London, Dr H G Hodgson, radiologist to King's College Hospital, introduced a discussion on the future of radiologic diagnosis. He said that coming radiologists must equip themselves with a wider and more extensive basis in pathology and clinical medicine. They must be able to talk to the neurologist, laryngologist, bacteriologist and other specialists in their own language and have a full knowledge of their difficulties. In the future, hospitals would demand that radiologists should have the same higher qualifications as their physicians and surgeons. The progress of x-ray technic would take place along two main lines—increased anatomic detail due to teleroentgenography and increasing refinement of opaque materials. He referred to a rotating target tube which had six focal spots of the smallest possible size, through which only a fraction of the total discharge passed. Thus a much heavier current could be used without injury. This tube had the advantage of the finest possible focus. Recently useful work had been done in the study of the gastro-intestinal mucosa by small quantities of barium sulphate with a technic whereby the rugae were outlined. Another useful method was the filling of the colon with barium sulphate, which was afterward siphoned off and air injected, so that abnormalities not previously revealed, such as polypi, became visible.

Sir John Rose Bradford

The death of Sir John Rose Bradford, F.R.S., past president of the Royal College of Physicians, has removed one of the leading figures of English medicine. Born in London in 1863, he was educated at University College, where after a distinguished career as a student he joined the staff. His earliest work was physiologic. In conjunction with Bayliss he wrote on electrical changes in secreting glands. The action of drugs on the circulation and secretion of the kidney, the innervation of blood vessels, the results of partial nephrectomy, and the influence of the kidney on metabolism were other subjects. On the basis of his physiologic work he became the leading authority on disease of the kidney. In Allbutt's "System of Medicine" he wrote the articles on the general pathology of the renal functions and on nephritis, and in Allchin's "Manual of Medicine," those on rabies, the mycoses and diseases of the ductless glands.

A Device for Viewing Operations

At St Bartholomew's Hospital a device has been adopted to enable more persons to view a surgical operation. A mirror with a universal joint is attached to the arm of the lamp. After the field of operation is illuminated and ready for the surgeon, the mirror is adjusted to the angle that gives most visibility to those not immediately concerned with the operation. In the ordinary way the surgeon and his assistants so block the visibility of the field that others can get only an occasional glimpse. The use of the mirror enables a larger audience to view the operation and has proved satisfactory.

April 26, 1934

Character and Treatment of Scleroderma

Leriche reported, at the January 16 meeting of the Societe de chirurgie, his experience in forty-six cases of scleroderma, in thirty-two of which operation had been performed. Scleroderma, although its chief clinical manifestation is a thickening of the skin, is primarily a skeletal disease, in which, under the influence of a hyperparathyroidism, the skeleton liberates calcium constantly and abnormally, thus depriving the body of its calcium reserves without replenishing them. The skin accumulates a portion of this free calcium, so that one often sees a scleroderma associated with Raynaud's disease and arthritis deformans. Therefore scleroderma is an endocrine dysfunction, affecting specifically the parathyroids. Scleroderma is not a sympathetic trophoneurosis. The sympathetic is simply an intermediary in the mechanism of production of the scleroderma. The parathyroid hormone causes vasomotor disturbances of a hypertonic type at the periphery; hence sympathectomy is efficacious. Since 1922, Leriche has operated in thirty-two cases. He excludes advanced sclerodermas with mummification, cases presenting bronzed skins and marked asthenia, and cases of scleroderma of the extremities of the edematous type, in all of which the operation is of no avail. Operation is indicated in all other forms, especially in the slowly developing cases with multiple skin areas (rather than in generalized cases) with the exception of those involving the abdomen. If there is hypercalcemia and elective localization in a young woman, he advises unilateral parathyroidectomy or a resection of both inferior thyroid arteries. If the patients are young and do not have lesions that are far advanced, one ought also to perform a periarterial sympathectomy. If the lesion is of long standing ganglionectomy or division of the rami is the better operation. The various operative procedures have given some highly gratifying results. Three patients have been well for more than ten years.

Examination of Students for Pulmonary Tuberculosis

At the February 12 meeting of the Academy of Medicine of Paris, Prof M L Saye of the University of Barcelona, Spain, reported the results of the examination of 637 first year students, varying in age from 17 to 20 years. Students were grouped as suspects if they had been exposed to infection in their homes during the preceding ten years or if roentgenoscopy or roentgenography revealed old lesions of the apexes or large tracheobronchial lymph nodes or if they had a pleurisy with effusion during the ten year period prior to matriculation. There were 126 of the 637 in this group of suspects while in thirty-three cases a definite pulmonary tuberculosis was found. In five of these thirty-three cases the students knew that the disease existed, two suspected such a condition and twenty-six did not. In twenty-six of the thirty-three cases the lesions were incipient. In five they were moderately and in the other two far advanced.

A comparison between roentgenoscopic and roentgenographic diagnosis revealed the latter as being far superior. In 42 per cent the roentgenoscopy was inadequate, while in 30 per cent lesions were discovered on the films that were not visible on simple fluoroscopic examination. In the discussion, Rist emphasized the necessity of subjecting all first year students to such complete physical examinations.

The Treatment of Malignant Neoplasms with Snake Venom

At the February 5 meeting of the Academy of Medicine, Lavedan reported fifty-one cases of cancer, located in various parts of the body, treated with cobra venom. Every patient received a minimum of four months of injections. Forty-five were cases presenting local or metastatic recurrence following

either operation alone, or high voltage roentgen therapy alone or both. In six cases, no previous treatment had been given. The initial dose was 5 mouse units three times a day every forty-eight hours. After every third injection the dose was increased by 5 units up to 50 units. When the latter dose was reached, the injections were given twice a week. No complications were observed unless the venom was injected directly into a vein. The injections seemed to have no bad effect on the kidneys, but when bleeding was present it seemed to be increased, so that in cancers of the uterus one was obliged to discontinue the injections during the menstrual period.

In only about one tenth of the cases did the cobra venom have any influence on the pain, so that there is no reason why, in incurable cancers, one should not prefer to give morphine in gradually increasing doses rather than to attempt to alleviate the pain with a preparation such as cobra venom, the action of which is inconstant. The effect on the general condition is psychic. Just as after injections of lead, copper and streptococcus toxins, there is a temporary feeling of well being, of renewed force and a return of the appetite. This lasts about as long after cobra venom injections as after the other substances. The cobra venom has no influence on the development of the growths even when the injections are made directly into the tumor. Histologic study of such injected superficial tumors shows that the neoplastic cells retain all their vitality, the mitoses being just as numerous as though no injection had been made.

Late Recurrence of Cancer

At the February 26 meeting of the Academy of Medicine eight cases were reported by Prof. Henri Hartmann of recurrences of cancers operated on from nine to forty-three years previously. In four cases of cancer of the breast recurrence took place nine, sixteen, twenty-two and forty-three years after operation. In the case in which operation had been done forty-three years before, the patient was now 92 years old and a slowly developing malignant ulceration was taking place in the operative scar. In one case of cancer of the body of the uterus, recurrence was noted in the vaginal cicatrix thirteen years after complete hysterectomy. In a second case, treated on two occasions with radium for a cancer of the cervix, a recurrence was found in the vesicovaginal septum thirteen years later. In a case in which a resection of the rectum had been performed, a cancer of the ascending colon developed seventeen years later. In a case of pylorotomy for cancer, performed in 1904, radiography in 1931 revealed an extensive carcinomatous involvement of the stomach.

Professor Crouzon, Professor Johannsen and Lord Moynihan Elected Members of Academy

At the February 20 meeting of the Academy of Medicine, Professor Crouzon of Paris was elected fellow and Professor Johannsen of Sweden and Lord Moynihan of England were elected nonresident fellows. Such an election is considered a great honor and is in recognition of especially meritorious contributions to medicine.

Vaccination Against Yellow Fever

At the February 19 meeting of the Academy of Medicine, Prof. Charles Nicolle, whose research work on yellow fever is familiar to American bacteriologists, reported the results of the vaccination of 3,000 persons in the West African colonies of France. Each of these 3,000 natives has received three inoculations of the vaccine, that is, the full dose. A still larger number of Europeans have already been given one or two inoculations. The method is absolute, innocuous and highly efficacious much more than the administration of a serum against yellow fever. Professor Nicolle believes that serotherapy should be abandoned in favor of vaccination.

(From Our Regular Correspondent)

March 25, 1935

Cancellation of Professors' Certificates

The decision of the federal ministry for art, science and education, following a controversy in regard to the theory of racial origins, to deprive Privatdozent Dr. K. Saller of the *venia legendi*, has caused a stir in academic circles. Saller was an accredited instructor in ethnical science and an assistant in the Anatomic Institute. He had specialized, for years, in anthropologic and kindred studies. His articles and books were esteemed for their value without reference to political problems, although his point of view on racial questions did not agree with the *Rassenpolitisches Amt* of the national-socialist party. In his farewell speech to the students, Saller, who as an instructor had taken the oath to support Hitler, said: "Races are not something absolutely rigid, something that has existed since primeval days. They are in a constant state of flux, sometimes increasing their diversification and sometimes passing through processes that tend to eliminate their differences. Racial differences are not manifested solely by physical characteristics but also by mental traits. In the process of time, our German race developed from previous races, and it has become entwined with the other modern races." The *Rassenpolitisches Amt*, however, issued a statement that the "state cannot approve the continuance in their posts of teachers who, by improper use of their scientific point of vantage, are endeavoring to break down and destroy the results of racial unity that are based on a common biologic foundation." From the beginning, Saller has refused to consider the political aspects of racial research, and in 1932 he expressed his disapproval of the existing views on race problems. Saller had stated that his love of truth and his sense of honor as a scientist would prevent him from renouncing his views. Judgment has been passed on him without a hearing, and he has voluntarily resigned his post. Dr. Gross, a physician and the director of the *Rassenpolitisches Amt*, has stated that "party and state cannot allow any person, under the cloak of an ostensibly scientific post, to exert a disturbing influence on the training of German youth in a uniform national and racial mode of thinking while, at the same time, possible reference may be made to national socialism and to its leader."

In addition, Dr. Arthur Kronfeld, who, although a Jew, has been able to hold his position as extraordinary professor in psychiatry at the University of Berlin, by reason of having fought at the front in the World War, has now been deprived of the *venia legendi*. According to the new regulations concerning habilitation (*THE JOURNAL*, April 6, page 1259), the minister of public instruction may withdraw or restrict the *venia legendi*, "if it seems desirable in the interest of the university." No explanation for the order was given. A special decree of the same minister excludes the 'non-Aryan' university instructors (there are a few who have retained their posts by reason of having fought at the front in the World War or for other specific reasons) from service on the examination boards. The *Deutsche Dozentenschaft*, the organization of the university instructors, has conveyed to the minister its expressions of gratitude for his action in this matter.

The Crusade Against Lupus

Professor Stühmer, ordinarius in dermatology at the University of Freiburg, who was chosen to promote the crusade against lupus in a region of southwestern Germany, published recently a report. A publicity campaign revealed an increasing number of patients, so that at the close of the campaign, Oct. 1, 1934, 2,800 lupus patients were under treatment, mostly of a severe type. The incidence of lupus is placed at one patient per thousand of population. In Westphalia, where the crusade has been best organized and under way for nearly nine years, the number of grave cases continues to increase. In Baden Stühmer dis-

covered in a short time more than 400 lupus cases in the vicinity of Freiburg. It appears that in the Black Forest area there is a relatively large number of severe cases.

The Public Health Services

Beginning April 1, the public health services of Germany will take on a more uniform character. The federal minister of the interior has issued detailed instructions. The public health services in the larger cities and districts will be expected to accomplish the following five main tasks: (1) to observe the health conditions, (2) to watch over the applications of health legislation, (3) to render expert opinions to all competent authoritative bodies in matters pertaining to public health, and to submit to them plans for the promotion of public health, (4) to make the examinations and research needed for the application of the regulations affecting the preservation of purity of race and the prevention of hereditary defects in future offspring, and (5) to issue certificates in all cases in which the presentation of an official medical testimonial is required. The physicians in the public health services should take every opportunity to familiarize themselves with local conditions affecting the public health and should endeavor to combat ignorance and prejudice on every hand. The public health services must bring to the attention of the proper authorities all violations of health regulations. Physicians of the public health services are given admission to all places over which they must exercise supervision. They are assured also of the close cooperation of other official boards, the local police force, and the health forces of the national-socialist party. Full time health officers may have private patients and may serve as medical advisers to certain bodies, but they will not be permitted to participate in general panel practice.

Creation of Roentgenologic Archives

In Berlin the health insurance societies, in association with the competent medical organizations, have established a system of roentgenologic archives at the headquarters of the *Verband der Krankenkassen*. The panel physicians must return (following their use) to the physicians who have made a roentgenologic examination all the films received from them. Every three months the director of the roentgenologic archives will secure from the roentgenologists all the films, together with the observations made thereon, of the members (including their families) of the large Berlin *krankenkassen*. The films will be classified and preserved.

Possibilities of Resuscitation After Apparent Death

At the University of Königsberg, Professor Bruns instituted experiments in connection with poisoning from carbon monoxide and from illuminating gas, to determine electrocardiographically the final cardiac standstill after breathing has ceased. It was found, in a number of animals that the electrocardiograph recorded action currents for about half an hour after disappearance of the heart tones and the pulse. The value of resuscitation methods was tested by the electrocardiogram. Only in unconscious persons with preserved corneal reflexes and demonstrable (though only weak) respiration and heart action do irritations of the skin or the mucosae (such as are employed in resuscitation attempts) reach the vital centers in the spinal cord or the heart itself. Artificial breathing has no effect on clinical cardiac standstill unless at the same time, it constitutes a stimulus to the heart action. Through the expiratory contraction of the chest a flow of blood from and to the veins of the thorax and in the pulmonary vessels is brought about. These movements of the blood are, at the same time mechanical irritations that bring about contractions in the endocardium, as is shown by the electrocardiograph. An indirect heart massage produced by thumping and agitating the heart region (seventy times a minute), by rhythmic elastic blows and by the short application of pressure likewise gives rise to action cur-
